| Validation:                   | The District shall retain a Registered Geotechnical Engineer to verify compliance with this measure.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| SP-29 Managen                 | nent of Hazardous Materials/Waste During Construction                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Description:                  | Prior to construction and during design, the District shall retain a Registered Geologist or Registered Environmental Assessor to survey each pipeline alignment for contaminated soil, recording the location, extent and type of contamination.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|                               | Construction activities related to the project that require excavation or<br>exposure of soil in areas suspected of containing soil or groundwater<br>contamination (i.e. areas in the vicinity of hazardous materials/waste<br>release sites) shall include monitoring by the contractor for subsurface<br>contamination in compliance with the appropriate state's (California or<br>Nevada) occupational safety and health regulations. This monitoring<br>would, at a minimum, include visual observation by personnel with<br>appropriate hazardous materials training, including 40 hours of<br>Hazardous Waste Operations and Emergency Response (HAZWOPER)<br>training as required for workers engaged in hazardous waste operations.                                                                                                                                                                                                                                                                                                                                            |
|                               | In areas where contamination of soil and groundwater is suspected or<br>known, groundwater brought to the surface as a result of dewatering shall<br>be contained in Baker tanks or similar containment devices. At a<br>minimum, this would allow the suspended solids associated with<br>dewatering to settle out before discharge, if discharge is allowable.<br>Depending on the proximity to known contaminated plumes, and the<br>probability of groundwater being contaminated based on visual or other<br>evidence; samples would be collected and analyzed. A State of<br>California (or State of Nevada) certified hazardous waste laboratory<br>using EPA-approved analytical methods should perform the laboratory<br>analyses. The types of analyses should be based on the likely<br>contaminant(s) and on local permitting requirements. Discharges of<br>dewatered groundwater would be subject to permitting by Lahontan or<br>NDEP. The origin of the contaminated materials shall dictate the<br>applicable State OSHA regulations and remediation process to follow. |
|                               | District shall obtain required permits and incorporate permit                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

District shall obtain required permits and incorporate permit requirements in the demolition/construction documents so that permit restrictions can be included in contractor's scope of work.

| SP-30 Pre-constru<br>Wildlife Nu | uction Surveys for <u>Migratory Birds</u> , Nesting Raptors and rseries                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |  |  |  |  |

**Description:** Potential active nest sites and wildlife nurseries within 0.25 mile of the construction zone shall be identified during pre-construction surveys. Construction activities within 0.25 mile of active nests shall be scheduled to occur outside of the nesting season, or exclusion zones shall be established and monitored during construction.

District shall retain a wildlife biologist to conduct a pre-construction survey to determine if raptor nests, <u>migratory bird nests</u>, and pygmy rabbit nursery sites occur in or within 0.25 mile of the project site. If construction takes place outside the breeding season there shall be no need to conduct surveys for active nests and nurseries. If no active nests or nurseries are found in the study area, no mitigation shall be required.

If nests or nurseries are found in the project area, construction exclusion zones shall be established in consultation with the CDFG around each active nest or nursery. No disturbance shall occur within the exclusion zone around a nest site or nursery during the breeding season. A biological monitor shall be present during construction that takes place during the breeding season within 0.25 mile of a nest site or nursery.

| South Tahoe Public Ut | tility District Recycled Water Facilities Master Plan                                                                                                                                                                                                                                                                      |

#### SP-31 Pre-Construction Marking and Fencing of Sensitive Native Plant Communities

| Description: | Mark and fence sensitive native plant communities prior to construction.                                             |  |  |  |  |
|--------------|----------------------------------------------------------------------------------------------------------------------|--|--|--|--|
|              | Pre-construction marking and fencing of sensitive native plant                                                       |  |  |  |  |
|              | communities is required to protect these resources during construction<br>and to avoid additional costly mitigation. |  |  |  |  |
|              |                                                                                                                      |  |  |  |  |

This mitigation measure parallels standard practice SP-31, Preconstruction Marking and Fencing of Wetlands and Riparian Habitat, but differs from the latter in that marking and fencing focus on the protection of native rangeland from construction disturbance. A revegetation specialist shall mark the boundaries of native rangeland using temporary signs, protected from damage by the weather, to alert construction crews that they have reached the boundaries of their construction site, and may be encroaching on native rangeland.

Native rangeland shall be fenced from the permanent District easement and/or property with temporary rope and flagged fencing visible from the cab of heavy equipment, to keep operators from encroaching on native rangeland outside of the construction easement.

The revegetation contractor shall remove the markings and fencing during the habitat restoration and revegetation of disturbed sites. Through its land agents, the District shall work with private landowners and public agencies to replace or repair range fences disturbed by construction.

| Validation:                 | USACE and CDFG                                                                                                                                                                                                                                                                                                |  |  |

#### **D.5.3 Operation and Maintenance Measures**

This section contains standard practices to be implemented during operation of the Project. These measures generally require monitoring of system operations over time and the modification of those operations to reduce adverse environmental impacts. Compliance with these measures will result in the avoidance and/or reduction of adverse environmental impacts.

#### SP-33 Surface and Ground Water Protection Plan

# **Description:** Install additional groundwater monitoring wells and monitor groundwater levels. Develop a Nutrient Management Plan (NMP) in accordance with the final draft of the State Board's Recycled Water Policy. Implement tailwater management and containment practices. Practice release prevention and public protection measures. Develop a monitoring response plan specifying appropriate actions to be taken at each site in the event of groundwater contamination or impending degradation of groundwater quality.

#### Alpine County Groundwater Monitoring Program

The District shall modify the Alpine County Groundwater Monitoring Program (ACGMP) to the satisfaction of Lahontan to offer concrete responses when baseline nitrate or other nutrient levels from groundwater monitoring wells show degradation of groundwater quality attributable to the recycled water reuse. The proposed modifications to the existing monitoring program are outlined in Appendix J of this EIR.

Nutrient Balance Comparison. Groundwater samples shall be collected from existing and new monitoring wells that shall be located at various distances down gradient from the portions of the project area that shall be irrigated with recycled water. The nitrate concentration in the groundwater shall be monitored quarterly, and compared to the previous year's data, and the threshold of 7 mg/l for nitrate. The drinking water standard (threshold) is 10 mg/l. The District shall commit to monitor for a "trigger threshold" of 7 mg/l allowing for alternative management opportunities prior to reaching the regulatory threshold. The plan shall include measures to curtail recycled water flows on to the project area either temporarily or permanently, should groundwater degradation result.

In order to determine the hydraulic loading based on nitrogen, Wood Rodgers consulted "WTS-1B: General Criteria for Preparing an Effluent Management Plan," prepared by the Nevada Department of Environmental Protection (NDEP). Wood Rodgers set a conservative "red-flag" threshold level of 7 mg/l for Cp, as is common practice in developing a Nevada Effluent Management Plan (EMP). This was done to insure that the receiving groundwater resource will not be excessively degraded to a point where it is no longer useable (please also refer to the Assimilation Capacity Technical Report, Appendix 4). The District understands that State Water Boards may impose a more stringent trigger value if an additional factor of safety is desired.

#### **Tailwater Management and Containment Practices**

<u>Tracking</u>. The District shall be required to track the quantity of recycled irrigation water applied to each irrigation area. The District shall be required to record total volume released for irrigation. The District shall create a log to track the irrigation within each irrigation area. The log shall indicate the date, area irrigated, irrigated acreage, start time, stop time, and comments.

<u>Tailwater Management.</u> The District shall apply recycled water for agricultural irrigation purposes inclusive of tailwater management. The following procedures shall be used to manage tailwater when irrigating with recycled water. Attend irrigation of fields and stop flow as water advances toward the end of the field to manage tailwater. In the event that tailwater is generated, containment can be accomplished by two methods, depending on the location of the field. Water can be conveyed by ditch and released for irrigation on a downstream field, or water can be contained by closing check gates and impounding the water in the containment area. A tailwater containment area shall be located on the property (size and location to be determined).

<u>Tailwater Return.</u> The District shall use the recycled water for agricultural purposes with tailwater management to ensure no discharge to surface water systems. The following procedures shall be used to contain tailwater, if generated from the project area when irrigating with recycled water: Irrigation shall be managed to optimize irrigation efficiency. Personnel shall attend irrigation of the fields to ensure that flows are stopped when irrigation demands have been met to avoid tailwater generation from the fields. Fields may be designed so that tailwater from upper fields flows onto lower fields as irrigation. All tailwater reaching the low end of the project area shall flow into a tailwater recovery area with a capacity to be determined to prevent surface discharge from the site when irrigating with recycled water.

<u>Winter Operation</u>. Recycled water shall be stored in Harvey Place Reservoir until it is needed at the beginning of the irrigation season. As such, winter irrigation shall not be authorized. Temporarycontainment of recycled water from HPR to the Diamond Valley Ranch may be authorized if approved by Lahontan.

#### **Surface Water Quality Protection**

To prevent contamination of freshwater sources from the aerial application of recycled water, the following buffers shall be applied when delineated irrigable acreage within the Project Area:

- A 25-foot setback from District property lines along Diamond Valley Road. Currently, irrigation occurs up to the property line along Diamond Valley Road. An overestimation of the buffer, which considers a 25-foot setback, allows the District discretion on irrigation methods.
- A 25-foot setback from the center line of irrigation ditches. In the areas currently under consideration for irrigation by the District, piping or rerouting of freshwater away from the recycled irrigation areas is proposed. A 25-foot setback from the center of primary ditches will protect freshwater supplies.
- A 25-foot buffer from the edge of streams. A 25-foot buffer from the edge of the IC Flood Control Channel and Indian Creek is necessary to protect beneficial uses and preserve water quality of freshwater sources.

#### **Release Prevention and Public Protection Plan**

These guidelines are applicable to an aerial irrigation system.

<u>Release Prevention</u>. Recycled water shall be applied in a manner to minimize potential impacts to groundwater quality incorporating the following specific measures to minimize the potential for surface release from the reuse site and preserve groundwater quality.

Standing Water. Unnecessary ponding of recycled water shall be

avoided. In order to prevent unnecessary standing water, it is imperative that the irrigation system and tailwater recovery be operated properly. Standing water shall be minimized through the following means:

- Control of irrigation to prevent excessive tailwater;
- Use of laser leveled border strips irrigation;
- Manual control of pasture valves;
- Presence of an on-site irrigator monitoring surface irrigation progress; and
- Maintenance of perimeter ditches and tailwater containment area.

<u>Tailwater Recovery.</u> A tailwater recovery and return area may need to be constructed on the property. This area shall contain excess recycled water

<u>Unstable Ground Conditions.</u> The irrigation system shall be operated to minimize potential surface runoff by considering ground conditions before irrigating. Unsuitable conditions include frozen, saturated, or flooded soils. Fields shall not be irrigated during or immediately following significant precipitation events.

<u>Irrigation System Malfunction</u>. DVR personnel will inspect the irrigated areas to make sure the irrigation system is operational. Problems identified will be addressed and all necessary repairs will be completed promptly.

<u>Spill Response</u>. Spill response shall be required in the event of bypass or failure of check gate structures, breach of irrigation ditches, or breach of containment berms. Spill response shall entail the following:

- Shut down irrigation;
- Close check gates to retain irrigation on upstream or downstream fields; and
- Contain runoff and minimize off-site discharge by diverting water with temporary ditches, impounding water at topographic low spots, and/or constructing containment berms.

<u>Public Protection</u>. The following protection measures shall be implemented to assure public safety.

<u>Controlled Access</u>. The Diamond Valley Ranch has a perimeter fence defining the property boundary and locked gates shall restrict access to the reuse area.

<u>Public Notification.</u> The existing perimeter fence shall be posted with "No Trespassing" and "Warning Recycled water Do Not Drink" signs. Notification signs shall be placed at the access points and at minimum 500-foot intervals along the exterior fence line of application areas.

<u>Worker Notification</u>. Diamond Valley Ranch personnel directly involved with irrigating shall receive training and notification regarding possible

hazards and appropriate personal hygiene for working with recycled water.

Personal hygiene practices include:

- Do not drink the irrigation water;
- Do not use the irrigation water for washing;
- Always wash hands and face with clean water and soap before eating or drinking;
- Wear rubber gloves when working on the irrigation system;
- Minimize skin contact with recycled water;
- Treat cuts immediately before continuing to work on the irrigation system; and
- Report problems that might pose a risk.

#### **Nutrient Management Plan**

The District shall may require the development of a NMPs for the Carson Valley and Wade Valley portions of the project area to the satisfaction of the State Board's Recycled Water Policy. Nutrient management is the act of managing the amount, source, placement, form and timing of the application of plant nutrient and soil amendments. In the context of recycled water irrigation, the plan shall consider nutrient and salt concentrations present in recycled water when calculating fertilizer and irrigation application rates.

The plan must include a description of the best practicable treatment or control measures necessary to prevent nutrient or salt-related pollution or nuisance. The plan shall outline an approach towards education of contract irrigators regarding application of recycled water in an amount not exceeding the rate of uptake by planted crops. During the interim period prior to approval of NMPs, the District can reasonably control discharges of salts to groundwater by implementing nutrient management practices. Crop types and grazing management shall be determined according to site-specific conditions.

An NMP is primarily developed for use by the reuser as a current reporting mechanism and a future planning document. It is secondarily intended as a reporting mechanism for regulators. The purpose of the NMP is to provide guidance for irrigating with recycled water as follows:

- Provide a description of the recycled water delivery system and ancillary system components to inform responsible personnel of the system operation and capabilities;
- Identify responsibilities of the permittee/operator in the operation, maintenance and management of the recycled water reuse on the permitted site;
- Instruct system operators in the purpose and intended operation of components within the irrigation system under normal operating conditions and during emergency conditions. This report includes procedures for emergency response and notification; and

Annual monitoring and reporting requirements.

Application rates shall be determined in accordance with site-specific hydraulic loading levels for the avoidance of degradation of groundwater quality and of groundwater mounding or increases in groundwater levels that cause surface water discharge in a non-stream environment.

To adequately convey, apply and manage average daily flows projected for 2028, the Carson and Wade Valley portions of the project area must be able to assimilate approximately 1.0 million gallons per day (MGD) of recycled waters exported from the District's WWTP. This is the difference between the 5.8 MGD projected for daily flows in 2028 and the 4.8 MGD total flow (71.89 in/yr or 5.99 acre-feet/acre) that can be applied effectively on the 904 irrigable acres in Diamond Valley Ranch with no calculated risk to groundwater quality. This application rate exceeds the current 2008 discharge from the District's WWTP, but does not adequately address projected discharge through 2028.

#### **Effluent Management Plan**

For Component 2 recycled water will be made available to irrigators in Nevada. The District shall may assist irrigators in Nevada with the preparation of Effluent Management Plans following guidance in WTS-1B: General Criteria for Preparing An Effluent Management Plan, the NDEP white paper.

#### Diamond Valley Ranch Nutrient Management Plan

The District shall implement the NMP for the Diamond Valley Ranch (Wood Rodgers 2009).

<u>Application Rates.</u> The initially calculated maximum recycled water application rate is 71.89 in/yr, which equates to 5.99 ac-ft/ac for 904 irrigable acres, or a total flow of 1,765 Mgal/yr (4.8 MGD). This is the maximum allowable application rate that will meet the crop requirements as well as meet the District's objective to use the maximum recycled water for irrigation purposes. This application rate exceeds the current average daily discharge from the District's WWTP.

Below is a summary of calculated application rates to meet the crop requirements for alfalfa and pasture grass, the recommended crops for the Diamond Valley Ranch portion of the project area.

| Сгор          | Irrigation | Maximum Application<br>Rate (ac-ft/ac) |
|---------------|------------|----------------------------------------|
| Alfalfa       | Surface    | 5.99                                   |
| Alfalfa       | Spray      | 5.57                                   |
| Pasture grass | Surface    | 3.03                                   |
| Pasture grass | Spray      | 3.18                                   |

Livestock Grazing. Currently the Diamond Valley Ranch is irrigated with freshwater and grazed in the late spring through early fall by approximately 1000 head of cattle under a grazing permit with the District. Although the District Pasture (see Figure 1 in NMP) has not been subject to consistent grazing over the last seven years, chemical properties are not significantly different as compared to the areas of the Ranch that have been consistently grazed. Wood Rodgers professional opinion is that the level of grazing that is occurring on the DVR is moderate, dispersed, and managed based on availability of feed. Thus, under this freshwater management regime no one area or field will be impacted by the production of manure and associated input of nutrients under a freshwater irrigation regime. Under a recycled water regime there will be a small excess of nitrogen available (NMP Table 5, Appendix 1, Grazing Options tech Memo).

If cattle grazing shall continue within the irrigation fields/temporary containment basins (Component 11), it is recommended that the carrying capacity of the crop be determined and livestock use be limited to a moderate level on a rotation system. Carrying capacity is defined as the maximum stocking rate possible that is consistent with maintaining or improving vegetation or related resources. It may vary from year to year on the same area due to fluctuating forage production.

In lieu of amending the grazing timeframes, crop type, and manure management necessary for a nutrient neutral grazing regime, the District shall commit to removing cattle from portions of the Diamond Valley Ranch when irrigating with recycled water. The removal of cattle during a recycled water irrigation regime is determined to result in deficiencies in the "whole ranch nutrient balance" for Phosphorus, Potassium, and Nitrogen, which assures the protection of groundwater resources.

<u>Crop Management.</u> Existing vegetation on the Diamond Valley Ranch consists of pasture grass species. The wetter portions of the ranch support grass-likes such as Baltic rush and sedges. When reviewing soil physical and chemical characteristics with the vegetation the Ranch is currently supporting, there are no unique vegetation species or communities. In other words, the species that occur are what is expected for mountain meadow community types, and are closely tied to soil moisture conditions rather than soil texture and soil chemical properties. An important consideration in developing an NMP is to maximize nutrient uptake by the vegetation. Alfalfa and pasture grass shall be the were the crop types studied for the Diamond Valley Ranch reuse area specifically for nutrient uptake calculations. Other crop types may be considered, but similar studies must first be completed.

Recommendations for alternative crops are as follows:

- The District shall consider a mix of crop uses (hay, crop, and wetlands mitigation plant materials). This will allow the DVR a variety of revenue opportunities as well as opportunity to maximize nutrient uptake and effluent disposal.
- Another viable option is to practice hay production for harvest or grazing, or both. One cutting shall be harvested due to short growing

season from pasture hay fields, followed by grazing on irrigated stubble of that crop.

- The Diamond Valley Ranch NMP shall consider crop/plant alternative opportunities for nutrient uptake for the crops as determined by the District. Nutrient uptake is considered as a nutrient loss in the nutrient balance of the ranch under the effluent irrigation scenario. This analysis shall provide the District with information to be able to determine the crops they want to consider for production and maximize nutrient uptake and effluent disposal.
- Wetland sod shall be an alternative. Citations for the nutrient uptake of species that would grow in a non-open water situation are not available. If this shall be considered as an alternative, tissue samples will need to be collected on a current wastewater wetland site and compared to tissue samples of a natural site.

Nutrient Uptake. Final crop selection shall be dependent on growing season in the study area, availability of supplemental irrigation, the quality of the domestic wastewater with respect to the salinity tolerance of the crop, and market if the District determines that it is beneficial to produce a cash crop. In turn, the crop(s) selected shall be used to determine the hydraulic loading limit and water balance calculations. The hydraulic loading limit can be largely influenced by the potential of the crop to uptake nutrients, primarily nitrate. The water balance is primarily based on the need of the crop or the evapotranspiration rates and soil permeability rates. Nutrient uptake is considered as a nutrient loss in the nutrient balance of the ranch under the recycled water irrigation scenario.

A primary concern with recycled water application for agricultural irrigation purposes is maintaining ground water quality. In order to prevent nitrogen from leaching to groundwater, nitrogen uptake by plant species shall be used as a factor in computing hydraulic loading based on nitrogen as the limiting factor. Plants will uptake nitrate, the soluble form of nitrogen that is present in recycled water. Nitrogen uptake by alfalfa is well documented, and a value of 200 lb/ac/day is commonly used in hydraulic loading limit calculations (Metcalf and Eddy 1991). The value for nitrogen uptake by pasture grass, 80 lb/ac/day, is obtained from California Plant Health Association (2002).

<u>Hydraulic Loading</u>. The following is a summary of calculated hydraulic loading rates and irrigation application rate.

|         |            | Hydraul     | Irrigation<br>Application<br>Rate<br>ac-ft/Ac |           |      |
|---------|------------|-------------|-----------------------------------------------|-----------|------|
| Crop    | Irrigation | Consumptive | Nitrogen                                      | Soil      |      |
|         |            | Use         | Loading                                       | Permeabi- |      |
|         |            |             |                                               | lity      |      |
| Alfalfa | Surface    | 71.89       | 86.05                                         | 274.72    | 5.99 |
| Alfalfa | Spray      | 66.75       | 86.05                                         | 274.72    | 5.57 |

| Pasture | Surface | 70.49 | 36.33 | 274.72 | 3.03 |
|---------|---------|-------|-------|--------|------|
| grass   |         |       |       |        |      |
| Pasture | Spray   | 65.45 | 38.20 | 274.72 | 3.18 |
| grass   |         |       |       |        |      |

For the combination of alfalfa/ surface irrigation, the maximum annual nitrogen hydraulic loading rate will be:

71.89 in/yr 5,416 ac-ft/904 irrigable ac (5.99 ac-ft/ac) 1.95 Mgal/ac

The above calculations are based on the assumption that there are no additional inputs of nitrogen being added to the crop as fertilizer or as manure. The following are the necessary steps for calculation of the hydraulic loading for nitrogen.

1. Calculate "actual nitrogen loading" applied on a monthly basis from volume of recycled water applied, concentration of total nitrogen in recycled water used for irrigation, and factors accounting for nitrogen available for plant uptake. Nitrogen available from recycled water is based on a 20% loss to volatilization/denitrification and a 5% loss to leaching (ref hydraulic loading spreadsheets in the appendix) for a total loss of 25%.

2. Include any nitrogen added as commercial fertilizer to determine the "actual nitrogen loading." (Wood Rodgers recommends against application of nitrogen-containing commercial fertilizer since doing so would reduce the amount or recycled water that can be applied for irrigation).

3. Calculate "cumulative annual nitrogen loading" each month as the sum of the monthly "actual nitrogen loading" from the beginning of the year through each quarter.

4. The "allowable nitrogen loading" is the annual nitrogen uptake rate for the crop grown on the irrigated fields. Compare available nitrogen applied to the annual uptake rate by calculating the percentage on a monthly basis: monthly "cumulative annual nitrogen loading" divided by "allowable nitrogen loading."

Assimilative Capacity. Lahontan requested an Assimilative Capacity Model be completed as an element of the NMP. Wood Rodgers substantiates that nitrogen loading (as described above) accomplishes the same goal. No cumulative effect from nitrogen loading was observed (NDEP data for NMP) and conclusions are that the assimilative capacity of receiving waters will not be impacted when irrigating with recycled water from the WWTP.

<u>Recycled Water Irrigation Planning.</u> Wood Rodgers evaluated typical surface and aerial irrigation methods to determine hydraulic loading rates under a recycled water irrigation regime with the primary intent of maximization of nutrient uptake on the 904 irrigable acres on the Diamond Valley Ranch.

Irrigation shall typically occur between April 1 and October 15. Wood Rodgers' opinion is that the type of irrigation method chosen shall be dependent on the type of crop to be grown, capital budget for initial materials costs, operating budget for pumping if required, and labor if needed by the system. Surface irrigation and spray irrigation were examined as potential alternatives. Surface irrigation provides the highest benefit based upon maximizing recycled water use, and aerial irrigation provides similar benefits with less potential for tailwater.

#### **Monitoring and Reporting Requirements**

The District shall supply monitoring and reporting data to Lahontan in compliance with the Waste Discharge Permit.

<u>Monitoring</u>. Monitoring associated with the Diamond Valley Ranch and other reuse areas of the project area shall be performed as required by the Waste Discharge Permit (Revised Board Order R6T-2004-0010):

- Monitoring of irrigation volume and rate of application shall be performed through an automated metering devise. DVR personnel will collect readings in order to determine the 30-day average flow;
- Harvey Place Reservoir recycled water quality shall continue to be monitored;
- Groundwater quality shall continue to be monitored at the existing monitoring wells. New monitoring wells shall added in the vicinities of the reuse areas proposed for recycled water irrigation; and
- A nitrogen balance shall be calculated on an annual basis. The annual balance shall be compared to the initial calculation and the results of the previous year's balance, as well as the Diamond Valley Ranch receiving water thresholds of 7 mg/l.

In order to determine the hydraulic loading based on nitrogen, Wood Rodgers consulted "WTS-1B: General Criteria for Preparing an Effluent Management Plan," prepared by the Nevada Department of Environmental Protection (NDEP). Wood Rodgers set a conservative "red-flag" threshold level of 7 mg/l for Cp, as is common practice in developing a Nevada Effluent Management Plan (EMP). This was done to insure that the receiving groundwater resource will not be excessively degraded to a point where it is no longer useable (please also refer to the Assimilation Capacity Technical Report, Appendix 4). The District understands that State Water Boards may impose a more stringent trigger value if an additional factor of safety is desired.

<u>Reporting.</u> Monitoring data shall be provided monthly, quarterly, or annually as required by Lahontan and others.\_ Should an <u>unauthorized</u> discharge of recycled water occur, Lahontan shall be notified as soon as the release is identified and controlled (within 2 hours). A written report on the release/discharge and the methods used for mitigation shall be submitted to Lahontan. The report shall list:

- Date and time of discharge;
- Exact location and estimated amount of discharge;
- Flow path and bodies of water which the discharge reached;
- Specific causes of the discharge; and

| South Tahoe Public Utility District Recycled Water Facilities Master P | lan |
|------------------------------------------------------------------------|-----|
|------------------------------------------------------------------------|-----|

• Preventive and/or corrective actions taken.

<u>Sampling Protocol.</u> Sampling of the monitoring wells by the District shall follow the procedure outlined below:

- Document sampling on field data sheet;
- Measure depth to groundwater from the top of casing;
- Remove approximately three well volumes with bailer or pump (Do not contaminate the well or samples if using a bailer) and if a particular well is known to recharge slowly, pump well till casing is empty, allow well to refill then collect sample;
- Obtain sample bottles with preservatives from the laboratory; and
- Collect samples and immediately place them in a cooler with ice.

The following sampling for monitoring shall be completed:

<u>Recycled Water Sampling</u>. Samples shall be collected from Harvey Place Reservoir using containers, preservatives, and procedures recommended by the laboratory.

<u>Flow Monitoring.</u> Flow monitoring shall be done with a flow meter. Daily and monthly totalizer readings shall be recorded during irrigation. Readings shall be collected manually or electronically. Location of daily irrigation applications shall also be recorded to demonstrate appropriate distribution throughout the irrigation areas.

<u>Soils.</u> Soil samples in irrigated areas shall be collected and shall be analyzed as required by Lahontan. Given the high quality of recycled water discharged from theWWTP, it is recommended that soils be sampled every 3 to 5 years during recycled wastewater irrigation application.

<u>Vegetation</u>. If the District determines that it will be beneficial to produce a crop other than alfalfa <u>or pasture grass</u>, it is recommended that tissue samples be collected and analyzed annually to determine plant nutrient uptake specific to the reuse area. A plant sample protocol needs to be developed in coordination with Lahontan.

## SP-34 Application and Temporary Containment Infrastructure Maintenance and Monitoring

| Description:                                                       | The District shall prepare and implement a maintenance plan to monitor<br>application and temporary containment infrastructure using water meters,<br>coupled with quarterly visual inspection of pipelines and levees, and<br>inspection during and immediately after high runoff events. Public<br>works projects must be subject to periodic maintenance to prevent<br>degradation of surface water quality from slope and levee failure, or<br>impoundment spills. |
|--------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

#### **D.6 Recommended Mitigation Measures**

This section outlines the mitigation measures recommended in response to potential significant impacts identified in impact analyses for environmental resources. These mitigations are additive to those standard practices the District is already implemented or has formally committed to implementing. Compliance with these mitigation measures will result in the avoidance and/or reduction of adverse environmental impacts.

#### GW-1A Determine a Nutrient Neutral Grazing Regime for Diamond Valley Ranch Remove Cattle Grazing from Portions of the Diamond Valley Ranch Irrigated with Recycled Water

**Description:** The District shall amend the grazing regime to reduce Nitrogen loading if recycled water is used for irrigation on the Diamond Valley Ranch.

Grazing timeframe, crop type, and manure management shall be determined. To continue cattle grazing in the Diamond Valley Ranch in conjunction with application of recycled water, the carrying capacity of the crop shall-must be determined and livestock use be limited to a moderate level on a rotation system. Carrying capacity is defined in the Diamond Valley Ranch NMP as the maximum stocking rate possible that is consistent with maintaining or improving vegetation or related resources. The assimilative capacity of pasture grass and/or alfalfa under a central pivot, recycled water regime with consideration to grazing impacts and manure inputs shall-must be determined to assure that nutrient inputs are balanced with nutrient uptake and that ground water quality is protected. The Grazing Options Technical Memo of the Diamond Valley Ranch NMP recommends that manure be analyzed at a statistically accurate level to provide more precise nutrient inputs.

In lieu of amending the grazing timeframes, crop type, and manure management necessary for a nutrient neutral grazing regime, the District shall commit to removing cattle from portions of the Diamond Valley Ranch when irrigating with recycled water. The removal of cattle during a recycled water irrigation regime is determined to result in deficiencies in the "whole ranch nutrient balance" for Phosphorus, Potassium, and Nitrogen which assures the protection of groundwater resources.

|                             | Maximum Duration for Temporary Containment <u>Do Not</u><br>aximum Duration of Temporary Containment (100 Days)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |  |  |
| Description:                | The District shall determine the maximum duration of containment of recycled waters that will meet the needs of temporary containment situations without causing impacts to groundwater quality. Wood Rodgers recommends additional investigations be undertaken in the areas of the proposed temporary containment fields to determine the depth to groundwater during the spring, as well as during drier months. An adequate depth to groundwater separating the unlined bottoms of the containment fields from the unsaturated zone will assures that groundwater quality is protected during times of temporary containment and that potential impacts are reduced to a level of less than significant.                                                |  |  |
|                             | The one-dimensional mass flux equation calculated by Farr West<br>Engineering predicts that Nitrate-Nitrogen concentrations in water<br>bearing zones will not be significantly impacted under a worst case<br>scenario (100 days of containment during periods of saturated soil<br>conditions, typically from late May to late July).                                                                                                                                                                                                                                                                                                                                                                                                                     |  |  |
|                             | The District shall not temporarily contain recycled water on the Diamond Valley Ranch for more than 100 days. Findings from the project-level Nitrate-Nitrogen investigations (Appendix I-c) show that potential groundwater impacts resulting from the containment of recycled water for a period of 100 days could cause Nitrate-Nitrogen concentrations to increase by less than 2.0 mg/L in the underlying groundwater. The potential impact is dependent on the Nitrate-Nitrogen concentration in the temporarily contained recycled water and the permeability of the the soil materials underlying the containment field and is independent of the separation depth between the floor of the temporary containment fields and the groundwater table. |  |  |
|                             | The District shall continue groundwater monitoring as outlined in SP-33.<br>Should the temporary containment fields be put into use, the District<br>shall complete project-level monitoring at the site to calibrate the one-<br>dimensional mass flux equation.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |  |  |

#### SW-3 Develop Project-specific Nutrient Management Plan for the Jungle

**Description:** The District shall prepare and implement a nutrient management plan, as outlined in SP-33, for the portion of the project area referred to as the Jungle. Irrigation rates shall be balanced with the hydraulic loading levels determined for the site for the protection of surface water quality in the West Fork of the Carson River. The NMP shall include surface and groundwater protection and tailwater controls specific for the site conditions.

| Description:                 | Component 32 will construct a spillway channel for ICR that conveys reservoir spillage of freshwater around HPR to Indian Creek. These spills have the potential to cause bank erosion in Indian Creek and increase TSS. The District shall create and properly manage the riparian water treatment wetlands that shall be located downstream of ICR as part of Component 15. In order to reduce the impacts from phosphates and nitrates potentially flushed from ICR, Component 15 shall be constructed prior to component 32. |                                                                    |

#### BIO-1 Conduct Biological Resource Assessments

**Description:** A qualified biologist and botanist shall conduct planning level surveys at the proper time of year to identify special-status species that might occur within the Project area. If sensitive fish or wildlife resources or habitat is found, project redesign shall avoid these resources whenever possible. If it is not possible to avoid impacting special status species then the impacts shall be mitigated to a level that is less than significant.

Biological Resource Assessments are to accompany tiered CEQA and NEPA documents for individual projects. They shall be conducted up to one full year before significant planning and design occurs on any given project. The assessments shall be conducted by qualified biologists who shall assist environmental planners in preparing the sections on Biology for CEQA and NEPA documents. Each assessment shall be written in a letter style report to District well in advance of the NOP.

selected for tiered projects. The assessments would be part of Initial Studies tiered from the present CEQA document and Environmental Assessments pursuant to NEPA.

#### **BIO-4A** Fish Passage Structures and Deer Migration Corridors

**Description:** Design in-stream structures to allow the passage of fish and provide unfenced corridors and bridges to facilitate deer migration.

**Fish.** Project engineers shall consult with a fisheries biologist to design non-pipeline conveyance infrastructure to facilitate the passage of fish and aquatic invertebrates. Pipelines shall be designed and maintained to meet requirements of the USFWS and CDFG.

**Deer.** Project engineers and ROW agents shall work with private landowners and public agencies to design conveyance and temporary containment infrastructure and fencing required around recycled water application areas to allow the passage of migrating deer. The precise determination of bona fide deer migration routes shall be made by a project wildlife biologist, federal and State wildlife biologists, and State Game Wardens CDFG North Central Habitat Conservation Branch.

Upon determination that a conveyance or temporary containment component shall impact a deer migration route, the Project Engineer shall design facilities to meet requirements of the USFWS and the CDFG to allow the passage of deer. These structures shall be maintained or redesigned at the discretion of federal and state agencies in consultation with the District.

#### BIO-4B Schedule Construction to Avoid Breeding and Migrating Wildlife

**Description:** Construction activities shall be limited to periods when fish are not spawning or migrating or when deer are not migrating if such activities would affect fish spawning or deer migration.

A District wildlife biologist in consultation with federal and state agencies shall determine the construction windows that shall minimize the disturbance to breeding and migrating wildlife including Lahontan cutthroat trout and birds. Construction windows shall be established and written into construction contracts.

### BIO-5A Map Sensitive Native Plant Communities and Prepare Habitat Restoration Plan

**Description:** A qualified botanist shall conduct surveys to identify and map sensitive native plant communities that might occur within the project area. If a sensitive plant resource or habitat is found, a Habitat Restoration Plan shall be put together and submitted to the responsible regulatory and planning agencies for approval.

Mapping of sensitive plant communities (native rangeland, including piñon pine woodland) shall be conducted by a botanist on color aerial photographs at a scale suitable for planning level purposes. Polygons mapped in this way shall be field checked. Aerial photo-based vegetation maps shall become part of the preliminary design package for each project.

The first step in project design shall be to redesign or relocate elements to avoid native rangeland and piñon pine woodland. If redesign or relocation is not possible, the project engineer shall minimize impacts to native rangeland and piñon pine woodland to the greatest extent possible. If impacts are unavoidable then mitigation shall be provided which reduces the impacts below a level that is significant.

**Habitat Restoration Plan.** A qualified habitat restoration or revegetation specialist shall prepare a Habitat Restoration Plan at a level of detail sufficient for interagency review and public input. The plan shall contain a description of the sensitive resources to be impacted, including discussion of what species were present before construction takes place, and the regulatory framework for protecting the sensitive resource.

The Habitat Restoration Plan shall contain a planting palette, soil analysis (including a laboratory assessment of soil nutrients, particle size, nutrient sufficiency, and recipes for amendments); a conceptual planting plan, statement of performance criteria, and maintenance and monitoring plan.

|                      | Impacts Mitigated                                                                                                                                                                                                                                                                                               | Level of Significance                     |

| Description:         | Monitor habitat restoration sites for fi<br>reporting and remedial measures if the<br>BIO-5A are not met.                                                                                                                                                                                                       |                                           |

This mitigation measure parallels BIO-7 Monitor Wetland and Riparian Mitigation Sites, but differs from the latter by focusing on revegetation of native rangeland that may be disturbed by the project footprint. It differs from wetland and riparian mitigation in having less stringent performance criteria and 1:1 mitigation ratio (one [1] acre of native rangeland restored, replaced, or revegetated, for every acre disturbed or destroyed). Finally, this mitigation measure only restores or revegetates native rangeland but does not guarantee its preservation in perpetuity.

A revegetation specialist shall visit each construction site to photodocument the construction contractor's compliance with Best Management Practices and Erosion Control Measures. In addition, the revegetation specialist shall document hydroseeding, and in the case of piñon pine replacement, the survival of container stock, each year for a total of five (5) years. The monitoring shall bring to the attention of the District project manager, any deviations from the performance criteria set forth in BIO-5A.

For each project, the revegetation specialist shall prepare a preliminary revegetation report to be submitted to the District project manager, one (1) year after completion of construction. A final revegetation report shall be submitted at the end of five (5) years in the case of piñon pine replacement.

#### BIO-7 Monitor Wetland and Riparian Mitigation Sites

**Description:** Monitor wetland and riparian mitigation sites for five (5) years to include annual reporting and remedial measures if the performance criteria outlined in SP-24 are not met.

**Maintenance and Monitoring.** Regulatory compliance would be achieved by execution of a mitigation monitoring and maintenance plan developed by a botanist or habitat restoration specialist. Monitoring of restoration success would employ techniques of vegetation and groundwater analysis using fixed photo-documentation points, semipermanent vegetation monitoring transects using the line-intercept plant ecological method, and shallow groundwater monitoring wells. Monitoring would take place for a period of five (5) years. The main elements of mitigation area monitoring and maintenance would be:

- Retain a qualified biologist to monitor restoration success;
- Install shallow groundwater monitoring wells and survey against horizontal and vertical control;
- Monitor groundwater levels three (3) times annually in the shallow groundwater monitoring wells;
- Survey restored landscape against horizontal control;
- Produce as-built drawings;
- Install semi-permanent vegetation monitoring transects and collect baseline data;
- Establish permanent photo-documentation points;
- Carry out repair of faulty drip irrigation lines and replacement of failed nursery stock;
- Prepare annual, written monitoring reports to be submitted to the permitting agencies;
- Delineate the newly created wetland after four (4) years; and
- Recommend remedial steps, if needed, to the responsible party.

Maintenance of the created habitat would entail semi-annual pick-up of refuse, mending of drip irrigation lines, control of unplanned erosion, repair of infrastructure (fencing and interpretive signs), and re-planting of failed landscape plantings. A qualified biologist would prepare annual monitoring reports. These reports would be reviewed by District and forwarded to the USACE, Lahontan, and CDFG.

**Success Criteria.** The success of mitigation shall be ascertained from review of monitoring data and comparison of the data against criteria to

be agreed upon, in advance, by the regulatory agencies and District. The recommended criteria are:

- In the case of riparian woodland plantings, survival of three (3) out of every five (5) container tree and shrub stock planted at the beginning of the five-year period (= target survival criterion).
- In the case of wetlands to be created, documented presence of all three mandatory criteria (hydrophytic vegetation, wetland hydrology, and hydric soil characteristics) after five (5) years according to methodology in the 1987 Corps Manual.

Failure to meet the above criteria shall necessitate replacement plantings and could trigger another three (3) years of monitoring if required by the permitting agencies.

#### **Impacts Mitigated and Mitigation Level**

|                       | Impacts Mitigated                                                                                                                                           | Level of Significance                            |

| ARCH-1 Identification | on, Evaluation and Avoidance of C                                                                                                                           | Cultural Resources                               |
| Description:          | (a) Upon selection of Project Compor                                                                                                                        | nents, the treatment of cultural                 |

(a) Upon selection of Project Components, the treatment of cultural resources to be affected by the Project shall continue to be addressed under the Section 106 process of the National Historic Preservation Act.

(b) As part of the Section 106 process, consultation to address potential adverse effects shall involve, at a minimum, District, Alpine and Douglas counties, the Washoe Tribe of Nevada and California and the Nevada and California SHPO. If necessary, the ACHP and other parties, if appropriate, may be a part of this consultation process.

(c) A PA between these parties, executed pursuant to 36 CFR 800.14 (b). The PA shall govern the implementation of a program to avoid adverse impacts to cultural resources formally determined eligible to the NHRP. The PA may provide for a phased resource identification, evaluation, and data recovery program.

(d) Phase I - Field surveys and cultural resource identifications must be directed by qualified archaeologists/historians/architectural historians who fulfill the Secretary of the Interior standards, as set forth in 36 CFR Part 1210, Appendix C. These identification studies must be conducted in a manner consistent with 36 CFR Part 1210, Appendix B, and with the recommendations of the SHPOs.

(e) Phase II - Prehistoric and historic resources that may be affected by implementation of the preferred alternative shall be evaluated for National Register significance. A phased resource identification, evaluation, and data recovery approach shall be implemented, allowing for construction to proceed at those locations where there are no cultural resources that may be affected by the project as allowed by the SHPOs. Evaluation for National Register significance shall be based on criteria A, B, C, and D, as presented in the Section 106 Guidelines, and the resources' overall integrity of location, setting, use, design, materials, workmanship, feeling, and association must be addressed.

(f) Subsurface testing of a resource is often needed in order to answer questions about an archaeological site's eligibility for the National Register or to obtain data needed to make decisions about how to mitigate Project impacts on a site already determined eligible or placed on the Register. Testing is directed toward determining the site's boundaries, the depth of its deposits, and/or its basic nature and condition. Testing is completed when sufficient information has been gathered to make a determination of eligibility or a management decision (ACHP 1980). The PA shall set forth guidelines for the testing and the subsequent development of a detailed data recovery work plan (research design).

(g) Phase III - The PA shall call for the development of a treatment plan (considerations for assessment of significance of cultural resources and impacts to NRHP eligible properties). This plan shall be developed according to the ACHP's "Recommended Approach for Consultation on Recovery of Significant Information from Archaeological Sites" (ACHP, 1999). This plan shall include the following (ACHP 1980):

- (1) Specification of cultural resources to be studied within the impact area of the preferred alternative;
- (2) Development of pertinent research questions;

- (3) Establishment of study topics, springing from the research questions;
- (4) Establishment of study priorities;
- (5) Definition of data needs for each topic for study;
- (6) Description of methods to be employed in fieldwork and analysis for determination of historic significance. Architectural characteristics should be recorded consistent with the standards of the Historic American Buildings Survey (HABS) or the Historic American Engineering Record (HAER), as appropriate; and
- (7) Development of a policy for the treatment of NRHP eligible properties.

The PA shall provide for archaeological monitoring to guard against the discovery of unknown and/or buried resources. A qualified archaeologist, who meets standards of the Secretary of the Interior, shall conduct in-field monitoring during construction activities in areas of high archaeological sensitivity. Native American monitors may be present as determined by the Washoe Tribe of California and Nevada. In-field monitoring of unknown archaeological resources is discussed under Construction Mitigation Measure 2.4.7, Protect Undiscovered Cultural Resource Sites.

(h) The PA shall provide an opportunity for appropriate technical review of the data recovery work plan, usually by the SHPOs, and, where needed, by the ACHP and peer review by outside parties.

(i) Phase IV – Cultural resources and historic properties studies shall be carried out by or under the direct supervision of a person or persons meeting at a minimum the Secretary of the Interior's Professional Qualifications Standards (48 FR 44738-39) in the appropriate disciplines. Cultural resources and historic properties studies shall meet the Secretary of the Interior's Standards and Guidelines for Archaeology and Historic Preservation (48 FR 44716-44740). Reports prepared shall meet the published standards of the Office of Historic Preservation specifically, Preservation Planning Bulletin Number 4(a), "Archaeological Resources Management Reports (ARMR): Recommended Contents and Format" (December 1989).

(j) The District shall ensure that curation of archaeological materials and data attempts to conform to the Secretary's Standards and Guidelines, and the requirements of the Archaeological Resources Protection Act (PL 96-95), if applicable.

If mitigation is the responsibility of an out of state agency, a reciprocal agency agreement shall be made between California and Nevada SHPOs to assure monitoring and reporting responsibilities are agreed upon.

on: The District shall retain an archaeological monitor to be present during certain phases of Project construction. The monitor shall be a qualified archaeologist who meets Secretary of the Interior standards and who shall conduct in-field monitoring during construction activities in areas of known resources and areas of high archaeological sensitivity. When the in-field monitor is not present, construction personnel shall be made aware of indicators of cultural resources and shall report encounters to the in-field monitor. In the event of late discoveries, work at the location should cease until the in-field monitor has evaluated the finds and situation and provided recommendations for further procedures.

Level of Significance

South Tahoe Public Utility District Recycled Water Facilities Master Plan

If human remains are discovered, the county coroner must be notified as soon as is reasonably possible (CEQA Section 15064.5). There shall be no further disturbance to the site where the remains were found. If the remains are Native American, the coroner is responsible for contacting the Native American Heritage Commission within 24 hours. The commission, pursuant to Section 5097.98 of the Public Resource Code (PRC), shall immediately notify those persons it believes to be the most likely descendants of the deceased Native American. Treatment of the remains shall be dependent on the views of the most likely descendent.

#### D.7 Program Implementation and Monitoring

#### **D.7.1 Implementation**

The District shall be responsible for the implementation and administration of the MMP for the Project. Where necessary to ensure compliance with mitigation measures, the District shall include the performance of mitigation in its contracts with irrigators, recycled water wholesalers and contractors. The District shall designate a staff person to serve as coordinator of mitigation monitoring among the various government agencies, construction contractors, and other parties. This person (Coordinator) shall oversee implementation and monitoring of compliance measures, standard practices, and mitigation measures to ensure that they are completed to the standards specified in the EIR.

Duties of the Coordinator include the following:

- Coordinate with applicable agencies that have mitigation monitoring and reporting responsibility;
- Coordinate activities with the construction manager;
- Coordinate activities of in-field monitors;
- Develop work plan and schedule for monitoring activities;
- Coordinate activities of consultants hired by the District when such expertise and qualifications are necessary;
- Routine inspections and reporting activities;
- Plan checks;
- Assure follow-up and response to citizen inquiries and complaints;
- Develop, maintain, and compile Verification Report form(s);
- Maintain the Mitigation Monitoring Checklist or other suitable mitigation compliance summary; and
- Coordinate and assure implementation of corrective actions or enforcement measures, as needed.

#### D.7.2 Mitigations Outlined By Project Component and Master Plan Project Number

Table D-2 below outlines the mitigations that are required to be implemented for each component when constructed.

|                     | Table D-2           Mitigation Required for Projects and Components |                                                                                 |  |

## **D.7.3 Mitigation Monitoring**

The implementation of compliance measures, standard practices and recommended mitigation measures shall be monitored at two levels. The first level of monitoring is done through the use of a Verification Report. A sample Verification Report is shown as Table 2-4. This report is to be completed by the District for each mitigation measure. Frequency of report completion shall vary based on the type of mitigation measure. For example, measures that require modification of final design drawings shall require that the Verification Report be completed at the time the final drawings are completed and again when they are approved. In-field monitoring for activities such as pipeline construction through a stream may require that a Verification Report be completed daily.

Once a mitigation measure is completed and the measure needs no further monitoring or follow-up, the District shall complete a final Verification Report that includes evidence of completion, such as a final engineering drawing or a photograph of field activities. The District shall be responsible for maintaining completed Verification Reports. Copies of these reports shall be maintained at the District Offices.

If the Coordinator determines that non-compliance has occurred, the Coordinator shall deliver a written notice describing the non-compliance and requiring compliance within a specified period of time. If non-compliance still exists at the expiration of the specified period of time, construction may be halted and fines may be imposed upon the party responsible for implementation, at the discretion of the District.

The second level of monitoring shall be done through the completion of the Mitigation Monitoring Checklist, Table 2-5. The purpose of the checklist is to provide a summary for the District, other public officials, and concerned citizens of the status of the adopted mitigation measures. The Coordinator shall update the checklist quarterly (four times a year) by reviewing the Verification Reports and status of the mitigation measures. A copy of the most current Mitigation Monitoring Checklist shall be maintained at the District Offices.

## D.7.4 Mitigation Monitoring Status Reporting

The District shall compile a Mitigation Monitoring Status Report on an annual basis. The report shall be prepared by the Coordinator and contain the following:

- Mitigation Monitoring Checklist to provide the status of every mitigation measure;
- List of completed mitigation measures;
- List of non-compliance incidences, with action taken or required;
- Evaluation of the effectiveness of the mitigation measures;
- Recommendations for modifications to the MMP to improve effectiveness; and
- Required modifications to the MMP to comply with legislation and policies adopted in the previous year (e.g. newly listed threatened species).

The report shall be presented and reviewed at a meeting of the District's Board of Directors. The meeting shall be noticed in local newspapers and shall be open for the public to speak and present written evidence as to the effectiveness of mitigation measures.

# Appendix E - Comparison of Components

## Appendix E - Comparison of Components

This Appendix provides a summary of total impacts for: Project Components 1-32 (Tables E-1 through E-32); No Project Components (Table E-33 and E-34); and Alternatives 1, 2, 3 and 4 (Tables E-35 through E-39).

# Alternative 1 - No Project

Implementation of the No Project Alternative would result in 26 significant and unavoidable impacts. Table E-35 provides a summary of impacts of the No Project Alternative.

|                              | T                                                       | able E-35                                                                                          |                                                                  |           |

The significant and unavoidable impacts that would result under the No Project Alternative (Components NP-1 and NP-2) are:

Existing recycled and freshwater water system significant and unavoidable impacts:

- GEO-2 Will the Project Components be subject to ground rupture due to location near a surface trace of an active fault?
- GEO-3 Will the Project Components be located in areas with soils and groundwater conditions that are susceptible to liquefaction during an earthquake?
- GEO-4 Will earthquake-induced strong ground shaking damage the Project Components?
- HYDRO-1 Will the No Project Components cause flooding?
- HYDRO-2 Will the No Project Components cause stream bank erosion?
- BIO-1 Will the Project Components cause loss of individuals or occupied habitat of endangered, threatened, or rare fish, wildlife or plant species directly or indirectly?
- BIO-2 Will the Project Components cause loss of individuals of CNPS List 2, 3, or 4 plant species?
- BIO-3 Will the Project Components cause loss of active raptor nests, migratory bird nests or wildlife nursery sites?
- BIO-5 Will the Project Components have a substantial adverse effect on any riparian habitat or other sensitive natural community identified in local or regional plans, policies, regulations or by the California Department of Fish and Game or US Fish and Wildlife Service?
- BIO-7 Will the Project Components have an effect on federally protected wetlands as defined by Section 404 of the Clean Water Act or waters of the U.S. through direct removal, filling, hydrological interruption, or other means?
- SW-2 Will the Project Components cause numeric criteria to be exceeded at West Fork Carson River at Stateline?
- SW-3 Will the Project Components cause numeric and narrative-based criteria to be exceeded at West Fork Carson River in California?
- SW-5 Will the Project Components cause narrative-based criteria to be exceeded in Indian Creek below Harvey Place Reservoir?
- PHS-1 Will the No Project Components create a public health risk due to its use of recycled water?

## Alternative 2 - Project

Table E-36 provides a summary of impacts for the Project (Alternative 2). The significant and unavoidable impact categories that would result under the Proposed Project Alternative (Components 1 through 24 and 29 through 32) are:

- GEO-2 Will the Project Components be subject to ground rupture due to location near a surface trace of an active fault?
- GW-1 Will the Project Components degrade groundwater quality in the Carson Wade or Diamond Valleys?
- BIO-1 Will the Project Components cause loss of individuals or occupied habitat of endangered, threatened, or rare fish, wildlife or plant species directly or indirectly?
- BIO-2 Will the Project Components cause loss of individuals of CNPS List 2, 3, or 4 plant species?
- BIO-3 Will the Project Components cause loss of active raptor nests, migratory bird nests or wildlife nursery sites?
- BIO-7 Will the Project Components have an effect on federally protected wetlands as defined by Section 404 of the Clean Water Act or waters of the U.S. through direct removal, filling, hydrological interruption, or other means?
- ARCH-1(Components 29, 30, 31 & 32), Will the Project Components disturb known, potentiallyeligible National or California Register properties, including archaeological, historical, architectural, and Native American/traditional heritage resources?
- ARCH-2 (Components 29, 30, 31 & 32), Will the Project Components disturb unknown archaeological resources or human remains?
- SW-3 (Component 30) Will the Project Components cause numeric and narrative-based criteria to be exceeded at West Fork Carson River in California?

Impacts ARCH-1 and ARCH-2 pertain to Components 29, 30, 31, and 32 only because the area where these components are to be implemented has not been surveyed for cultural resources. Impact SW-3 only applies to Component 30.

# **Alternative 3 - Master Plan Recommended Projects**

Table E-37 provides a summary of impacts for the Master Plan Recommended Projects Alternative (Alternative 3). The significant and unavoidable impact categories that would result under the Master Plan Recommended Project Alternative are:

- GEO-2 Will the Project Components be subject to ground rupture due to location near a surface trace of an active fault?
- GW-1 Will the Project Components degrade groundwater quality in the Carson Wade or Diamond Valleys?
- BIO-1 Will the Project Components cause loss of individuals or occupied habitat of endangered, threatened, or rare fish, wildlife or plant species directly or indirectly?
- BIO-2 Will the Project Components cause loss of individuals of CNPS List 2, 3, or 4 plant species?
- BIO-3 Will the Project Components cause loss of active raptor nests, migratory bird nests or wildlife nursery sites?
- BIO-7 Will the Project Components have an effect on federally protected wetlands as defined by Section 404 of the Clean Water Act or waters of the U.S. through direct removal, filling, hydrological interruption, or other means?
- ARCH-1(Components 29, 30, 31 & 32), Will the Project Components disturb known, potentiallyeligible National or California Register properties, including archaeological, historical, architectural, and Native American/traditional heritage resources?
- ARCH-2 (Components 29, 30, 31 & 32), Will the Project Components disturb unknown archaeological resources or human remains?
- SW-3 (Component 30) Will the Project Components cause numeric and narrative-based criteria to be exceeded at West Fork Carson River in California?

# **Alternative 4 - Master Plan Trigger Projects**

Table E-38 provides a summary of impacts for the Master Plan Trigger Projects Alternative (Alternative 4). The significant and unavoidable impact categories that would result under the Master Plan Recommended Project Alternative are:

- GEO-2 Will the Project Components be subject to ground rupture due to location near a surface trace of an active fault?
- GW-1 Will the Project Components degrade groundwater quality in the Carson Wade or Diamond Valleys?
- BIO-1 Will the Project Components cause loss of individuals or occupied habitat of endangered, threatened, or rare fish, wildlife or plant species directly or indirectly?
- BIO-2 Will the Project Components cause loss of individuals of CNPS List 2, 3, or 4 plant species?,
- BIO-3 Will the Project Components cause loss of active raptor nests, migratory bird nests or wildlife nursery sites?
- BIO-7 Will the Project Components have an effect on federally protected wetlands as defined by Section 404 of the Clean Water Act or waters of the U.S. through direct removal, filling, hydrological interruption, or other means?
- ARCH-1 Will the Project Components disturb known, potentially-eligible National or California Register properties, including archaeological, historical, architectural, and Native American/ traditional heritage resources?

- ARCH-2 Will the Project Components disturb unknown archaeological resources or human remains?
- SW-3 Will the Project Components cause numeric and narrative-based criteria to be exceeded at West Fork Carson River in California?

## Impacts and Analysis

The three action alternatives would result in a total of nine categories of impacts: GEO-2, GW-1, BIO-1, BIO-2, BIO-3, BIO-7, ARCH-1, ARCH-2, and SW-3. Table E-39 below summarizes the number of resource impacts by alternative. It shows that the Project contains the highest number of significant and unavoidable impacts at 133, followed by the Master Plan Trigger Projects at 89, then the Master Plan Recommended Projects Alternative at 48 and the No Project Alternative with 26. While the number of resource impacts differs by alternative, the impact categories are the same between the action alternatives (Alternatives 2, 3, and 4). The degree of impact is directly proportional to the number of components that are included in each alternative. The Proposed Project would result in greater impacts to groundwater and biological resources than the other two action alternatives due to the greater number of components that would be implemented.

| Table E-39    |                                                         |                                                                                                    |                                                                  |            |  |  |  |

# **APPENDIX 4**

Assimilation Capacity Technical Report

# **EXECUTIVE SUMMARY**

Wood Rodgers was retained by the South Tahoe Public Utilities District (DISTRICT) to develop a nutrient management plan (NMP) for the Diamond Valley Ranch (DVR). The DISTRICT intends to use recycled water to irrigate the ranch.

Wood Rodgers collected site-specific soils data for the development of this NMP. The DISTRICT provided recycled water quality data (final effluent data from the plant as well as Harvey Place Reservoir data).

Wood Rodgers prepared four technical memoranda addressing Irrigation Methods, Crop/Plant Selection, Recommended Fields, and Grazing Options for the DVR. The recommendations developed in the Technical Memoranda are brought forward for consideration in the development of this NMP.

The purpose of the NMP was to determine the best combination of crop and irrigation method to maximize recycled water reuse and nutrient uptake while also protecting groundwater and surface water resources. Acknowledging the fact that the application rate would logically be different dependent on crop selection and irrigation method, several analyses were completed using different crops (alfalfa and grass hay) under both surface and aerial irrigation methods.

Wood Rodgers initial calculations considered crop consumptive use (irrigation demand), crop capacity for nitrogen uptake, and soil permeability to determine the maximum volume of recycled water that could be applied. This work is detailed in Section 5.0 of this Nutrient Management Plan. Results of the analyses determined that growing alfalfa with surface (flood/furrow) irrigation would maximize recycled water reuse and nutrient uptake, thereby meeting the DISTRICT's objective. Thus, the initially calculated maximum recycled water application rate was 71.89 in/yr, which equates to 5.99 ac-ft/ac for 904 irrigable acres, or a total flow of 1,765 Mgal/yr (4.8 MGD). This is the maximum allowable application rate that would meet the crop requirements as well as meet the DISTRICT's objective to use the maximum recycled water for irrigation purposes; however, this application rate exceeds the average discharge from the DISTRICT treatment plant. It must also be acknowledged that surface irrigation methods may result in runoff (tailwater) production. The tailwater can be used to irrigate subsequent areas and must ultimately be collected and contained at the final irrigation area. The DISTRICT may need to implement a tailwater management protocol to protect surface water sources, as discussed in Section 7.0 of this report, if surface irrigation is selected as the preferred alternative.

Given that the application rate calculated under the initial assumption exceeds the production of recycled water from the plant, the next step was to assume that the DISTRICT intends to reuse the entire annual volume of recycled water (total flow of 4.5 MGD or 1640 Mgal/yr, which equals 5,032 ac-ft) for irrigation every year with no net annual storage in Harvey Place Reservoir. Thus, this total water volume was then used

as the starting point to calculate the total available amount of recycled water that could be applied per month. Based on using the total 4.5 MGD per year, the nitrogen balance (Table 9 in Section 5.0) was developed to maximize uptake.

Based on this assumption (the DISTRICT intends to reuse the entire annual volume of recycled water), the recommended application rate calculated for growing alfalfa with surface irrigation would therefore be 66.80 in/yr, or 5.57ac-ft/ac for the 904 irrigable acres. (It should be noted this number is very close to the maximum allowable application rate for growing alfalfa with spray irrigation. Wood Rodgers is recommending surface as the preferred method due to the minimal capital and O&M costs). The nitrogen balance calculation is detailed in Table 9, located in Section 5.0 of this report. Once again, as with any surface irrigation system, there may be runoff and tailwater associated with surface irrigation and the DISTRICT may need to implement a tailwater management protocol to protect surface water sources, as discussed in Section 7.0 of this report.

Conversely, on the more conservative side, the DISTRICT could select an aerial irrigation method growing alfalfa with spray irrigation, with a maximum application rate of 66.75 in/yr or 5.57 ac-ft/yr, with minimal resulting tailwater.

Table ES-1, below, compares application rates for alfalfa and grass hay under surface and aerial irrigation methods.

| Crop          | Irrigation | Maximum Application Rate (ac-ft/yr) |
|---------------|------------|-------------------------------------|
| Alfalfa       | Surface    | 5.99                                |
| Alfalfa       | Spray      | 5.57                                |
| Pasture grass | Surface    | 3.03                                |
| Pasture grass | Spray      | 3.18                                |

Table ES-1. Summary of Calculated Application Rates

At the request of the DISTRICT, pursuant to a requirement from the Lahontan Regional Water Quality Control Board (Lahontan), Wood Rodgers prepared a brief technical report addressing Assimilation Capacity. The results of that report are included in Appendix 4.

This NMP also contains information related to recycled water release prevention, public protection, monitoring and reporting.

The DISTRICT acknowledges the proposed direction provided in the DRAFT November 4, 2008 Recycled Water Policy with regard to the management of salts and nutrients being on a basin-wide or watershed-wide basis. However, at the time that the DISTRICT commenced development of Diamond Valley Ranch NMP, this specific guidance had yet to be developed. The DISTRICT, being knowledgeable of forthcoming regulatory requirements, thought it prudent to embark on development of an NMP for DISTRICT owned property as soon as possible with an opportunity to bring the document into compliance with future regulations as they become accepted and implemented.

# 1.0 INTRODUCTION

South Tahoe Public Utilities District (DISTRICT) intends to use filtered secondary treated effluent from their South Lake Tahoe wastewater treatment plant (WWTP) for agricultural irrigation of the Diamond Valley Ranch. This nutrient management plan (NMP) is intended to provide adequate information for the DISTRICT to determine a recommended domestic wastewater application rate for agricultural purposes. This NMP considers and is dependent on variables such as recycled water quality, irrigation practices, crop selection, and protection of ground- and surface water resources. The NMP is also intended to be a "living" document, thus, it will be updated as needed to ensure that it adequately describes and represents current and proposed operations, maintenance, management, and emergency procedures related to the irrigation system. Proposed updates to this document will be based on annual monitoring results.

The State of California is in the process of developing regulations and guidelines for the land application of recycled water for agriculture. The Lahontan Regional Water Quality Control Board (Lahontan) regulates domestic wastewater reuse in Alpine County where wastewater reuse in this area is largely supplemental agricultural irrigation. The DISTRICT acknowledges the proposed direction provided in the DRAFT November 4, 2008 Recycled Water Policy with regard to the management of salts and nutrients being on a basin-wide or watershed-wide basis. However, at the time that the DISTRICT commenced development of Diamond Valley Ranch NMP, this specific guidance had yet to be developed. The DISTRICT being knowledgeable of forthcoming regulatory requirements thought it prudent to embark on development of an NMP for DISTRICT owned property as soon as possible with an opportunity to bring the document into compliance with future accepted regulations when that time came.

Wood Rodgers proposal anticipated that this NMP would be developed using the Natural Resources Conservation Services Nutrient Management 590. In researching the development of an NMP using Nutrient Management 590, it was determined that this guidance document is intended to be used when management (area to be used, crop to be grown, method of irrigation) is known. Given that the DISTRICT is in the "planning process" for future use of recycled at the Diamond Valley Ranch, we chose with the DISTRICT's approval to use existing guidelines. As such, the Diamond Valley Ranch NMP was developed using the Nevada Division of Environmental Protection (NDEP) guidance documents (*WTS-1B: General Criteria for Preparing an Effluent Management Plan*) and input from California Regional Water Quality Control Board. These guidelines are contained in Appendix 2.

An NMP is primarily developed for use by the reuser as a current reporting mechanism and a future planning document. It is secondarily intended as a reporting mechanism for regulators. The purpose of this NMP is to provide guidance for irrigating with recycled water as follows:

- Provide a description of the recycled water delivery system and ancillary system components to inform responsible personnel of the system operation and capabilities.
- Identify responsibilities of the permittee/operator in the operation, maintenance and management of the recycled water reuse on the permitted site.
- Instruct system operators in the purpose and intended operation of components within the irrigation system under normal operating conditions and during emergency conditions. This report includes procedures for emergency response and notification, and
- Annual monitoring and reporting requirements.

In addition, The Diamond Valley Ranch NMP is also intended as a report of findings and recommendations as requested by the DISTRICT. This NMP was also developed based on Technical Memos developed, reviewed and approved by the DISTRICT. These technical Memos are also presented in Appendix 1.

Immediately adjacent to the DISTRICT's disposal area in Alpine County, California, domestic wastewater operator/managers in Douglas County, Nevada, comply with current NDEP effluent management planning guidelines and monitoring standards and requirements for the safe reuse of treated domestic wastewater. Since this protocol has been largely successful in protecting the groundwater resources of the Carson River hydrologic basin (of which Diamond Valley is a part), this guidance document was selected to be the most appropriate current basis for determining recommended recycled water application rates for use by the DISTRICT on the Diamond Valley Ranch.

The results of the preliminary analyses indicate that growing alfalfa for harvest using surface irrigation will provide the greatest benefit to the DISTRICT for the least cost. Benefit used here means, the greatest opportunity for quantity of reuse of recycled wastewater and the greatest opportunity for nutrient uptake by the crop.

# 2.0 SITE DESCRIPTION

#### Background (From Harding ESE 2000)

In 1980 and 1998, the USDA Natural Resources Conservation Service completed two studies. Both of these studies covered the same project area and included Diamond Valley Ranch. Surface water features in the project area addressed in past work included the West Fork of the Carson River and Indian Creek as well as a complex system of ditches to convey irrigation water.

The first study (USDA 1980) was premised on the preferred alternative of converting the DISTRICT's reclamation plant to secondary treatment, and the potential impacts of use of the domestic wastewater for land application (agricultural irrigation). The first report concluded that use of the DISTRICT's secondary treated wastewater for agricultural irrigation under prudent management would not contaminate soil, surface water, or groundwater resources.

The second study (USDA 1998) was conducted as a follow up to the 1980 study. Since 1981, a monitoring program has been in place to collect water quality and soil quality data. This study completed an independent review and analysis of the data collected to date, and evaluated the overall impact of the use of domestic wastewater for land application. It concluded that some soil sites and some well sites showed nitrate nitrogen (NO<sub>3</sub>-N) accumulation. The values measured were below the critical thresholds but exhibited upward trends. Some of the soil site analyses reported accumulation of salts and sodium. The 1998 report also included Best Management Practices to reduce percolation of nitrates to the groundwater table. Disposal areas included Harvey Place Reservoir, Diamond Ditch, the two Fredricksburg Ditches, and the irrigated agricultural lands.

Harding ESE (2000) developed domestic wastewater application guidelines using USDA (1971) Soil Survey data. The purpose of this study was to determine the recommended application rates for reuse of domestic wastewater for agricultural purposes. More specifically, this was to be a tool that would allow the operator/manager to determine the recommended wastewater application rate for irrigation purposes based on varying soil texture characteristics, the crop that will be grown (irrigation requirement and salt tolerance levels), irrigation season, interval of application, and percentage mixing with fresh water.

The DISTRICT expressed an interest in obtaining a better understanding of appropriate agricultural application rates for domestic wastewater for their current disposal area in Alpine County, California, and potential disposal areas immediately to the north in Douglas County, Nevada. This interest was premised on the desire to exercise better management decision-making processes regarding where, how, and how much recycled domestic wastewater can safely be applied to a given area of land. Through the review of the two previous USDA NRCS studies and close coordination with DISTRICT personnel, it is the intention of this NMP to provide that understanding.

# 2.1 Communications and Staff

Hal Bird is the Land Application Manager for the DISTRICT. Recycled water and groundwater depth data are collected and analyzed by the DISTRICT laboratory.

South Tahoe Public Utilities District Hal Bird, Land Application Manager 1275 Meadow Crest Drive South Lake Tahoe, California 96150

Lahontan Regional Water Quality Control Board has direct regulatory jurisdiction regarding the use of recycled water in Alpine County, California. Robert Tucker is the Water Resources Control Engineer that coordinates with the DISTRICT.

# 2.2 Reuse Site Characteristics

## 2.2.1 Diamond Valley Ranch

The 2,500-acre Diamond Valley Ranch is located in eastern Alpine County, California, at the base of the Carson Range, just west of the Nevada-California state line. Highways 88 and 89 intersect at Woodfords, California a small town located within 3 miles of the Diamond Valley Ranch (Figure 1, Vicinity Map; Figure 2, Site Plan). The elevation of the Ranch property ranges from 5,400 to 6,100 feet. Average annual precipitation is approximately 19 inches (Western Regional Climate Center Markleeville, CA (045356). Please see Appendix 2, Table 1. Indian Creek Reservoir is located immediately to the south of the Ranch with the West Fork of the Carson River flowing to the north of the Diamond Valley Ranch. Prevailing winds are from the northwest.

The DVR is separated into 11 pastures (1 through 10 and the DISTRICT Pasture). These existing fields as presented in Figure 2 are largely delineated by existing fences, and are as designated by the DISTRICT.

To determine the area of potentially irrigable lands using recycled wastewater (Please see Recommended Fields Technical Memo, Appendix 1) on the DVR, Wood Rodgers considered areas that are either currently irrigated with fresh water and/or have been historically irrigated. The proximity of streams, irrigation ditches, springs, and areas of high groundwater, as well as infrastructure have also been taken into consideration. In addition, a sketch of the fields provided by Mr. Hal Bird was digitized into GIS. Based upon the topographic information provided by the DISTRICT associated with the May 15, 2008, aerial photography, the field boundaries were subsequently revised. The field boundaries were adjusted to follow the fence lines, streams, ditches, or roadways. The Field boundaries provide the overall framework for the quantification of potentially recycled water irrigable acreage at the DVR.

To prevent contamination of freshwater sources from the application of recycled water, the following buffers were applied in the determination of irrigable acreage:

#### A 25-foot setback from DISTRICT property lines along Diamond Valley Road.

Currently irrigation occurs up to the property line along Diamond Valley Road. An overestimation of the buffer which considers a 25-foot setback allows the DISTRICT some discretion on irrigation methods.

#### A 25- foot setback from the center line of irrigation ditches.

In the areas currently under consideration for irrigation by the DISTRICT, piping or rerouting of fresh water away from the recycled irrigation areas is being proposed, thus no buffers would be required. However, for planning purposes, the DISTRICT requests a 25 foot buffer from the center of the primary ditches.

#### A 25-foot buffer from the edge of Streams should be applied for planning purposes.

The line work in the ditches\_03.shp and streams\_03.shp files, as provided by the DISTRICT Engineering Department, formed the basis of analysis for the buffer areas. However, some of the line work in these files was adjusted based on the 2008 aerial photography and topographic data to more closely follow the alignments of existing water features. To provide a 25-foot buffer from the edge of the IC Flood Control Channel and Indian Creek, the top of the streambanks were approximated from the 2008 topographic data. A 25 foot buffer was created in GIS from the streambank linework.

The DISTRICT requested a 25-foot setback of irrigable lands along DISTRICT property lines extending along Diamond Valley Road. To determine the location of the setback, a 25-foot offset was applied to the DISTRICT Field boundaries. The 25-foot setback was not applied to areas designated as high groundwater nor areas defined as "Not a Part of Study". These areas extend to the DISTRICT Field boundary.

Areas of high groundwater were identified based upon field visits, aerial photography (USA Imagery, April 2007, © 2007 i-cubed. Boundaries and transportation: © 2006 ESRI, AND, TANA), the results of the August 2008 soil sampling, and DISTRICT groundwater monitoring data. Please see the Recommended Fields technical Memo contained in Appendix 1 for additional information.

Locations and areas designated as "Not a Part of the Study Area" in Figure 2 of this NMP either contain infrastructure prohibiting the application of recycled waters, are too small in area to manage as effluent reuse areas, or are constrained due to topographic conditions, or were not studied at this time.

#### 2.2.2 Recycled Water Supply (From Harding ESE 2000)

California state law requires the DISTRICT to export recycled water out of the Lake Tahoe Basin. Domestic wastewater exported from the DISTRICT's South Lake Tahoe plant has been used as supplemental irrigation water in Alpine County since 1968.

Until 1989, the DISTRICT exported tertiary treated effluent. As is common in the treatment process, the DISTRICT's tertiary domestic wastewater contained high concentrations of dissolved salts. Thus, the tertiary treatment was changed to secondary treatment in 1989 to reduce these concentrations. Secondary treatment resulted in lower concentrations of dissolved salts; however, higher concentrations of nutrients such as nitrates resulted. The State of California, Lahontan Regional Water Quality Control Board, and the U.S. Environmental Protection Agency regulate the quality of domestic wastewater as well as the quantity produced at the DISTRICT's plant.

Treated domestic wastewater was conveyed twenty-seven (27) miles from the DISTRICT's plant in South Lake Tahoe, over Luther Pass, to Indian Creek Reservoir in Alpine County. Harvey Place Reservoir was constructed to the north of Indian Creek Reservoir in 1989 for storage of domestic wastewater storage via an earthen dam. As a result, Indian Creek Reservoir was converted to a fresh water lake.

## 2.2.3 Recycled Water Quality

Recycled water quality data at the Wastewater Water Treatment Plant (WWTP) for the years 1980-2007 was provided by the DISTRICT, and is included in the Appendix 2, Table 2. Below in Table 1 is a summary of that data. In addition, water quality data for Harvey Place Reservoir (HPR) for the years 1989-2007 was provided by the DISTRICT and is contained in Table 3 of Appendix 2. Table 2 below presents a summary of that data.

The DISTRICT's HPR recycled water constituents were used to determine the recycled water application rates for Diamond Valley Ranch.

| BOD         | 5.1 mg/l            |  |  |  |
| SS          | 12.7 mg/l           |  |  |  |
| NO3-N       | 2.8 mg/l            |  |  |  |
| Total P     | 2.7 mg/l            |  |  |  |
| TDS         | 258 mg/1            |  |  |  |
| EC          | 490 umhos           |  |  |  |
| Total N     | 17.6 mg/l           |  |  |  |
|             |                     |  |  |  |

#### 2.2.4 Soils

The Soil Survey of the Carson Valley Area, Nevada-California and Douglas County, Nevada provide non site specific information and thus provide limited utility regarding the determination of an application rate and assimilative capacity for recycled wastewater reuse on the DVR. In order to provide more site-specific information, the soils that occur on the DVR were sampled in August 2008 to determine site-specific limiting physical and chemical attributes.

Sample locations and number of samples collected at each location is summarized in Table 3 below and locations are presented on Figure 2. Fields sampled, and the location of samples within those fields, was based on the DISTRICT's guidance regarding fields that would most likely be developed as irrigation fields.

| Table 5. Summary of Son Samples Conected |                              |                                       |  |
|------------------------------------------|------------------------------|---------------------------------------|--|
| Field Number                             | Sample Locations<br>18 Total | Samples per Location,<br>respectively |  |
| 1                                        | 2 A, B                       | 4, 3                                  |  |
| 2                                        | 2 A, B                       | 4, 4                                  |  |
| 3                                        | 1 A                          | 4                                     |  |
| 4                                        | 2 A, B                       | 3, 4                                  |  |
| 6                                        | 3 A, B, C                    | 5, 5, 4                               |  |
| 7                                        | 3 A, B, C                    | 4, 1, 3                               |  |
| 8                                        | 1 A                          | 3                                     |  |
| 9                                        | 2 A, B                       | 4, 3                                  |  |
| DP                                       | 2 A, B                       | 4,3                                   |  |

Table 3. Summary of Soil Samples Collected

Soil samples we submitted to AgSource Harris (Lincoln, Neb.) for laboratory analysis. A full suite of analyses was requested to be performed and the results are contained in Appendix 3.

#### 2.2.4.1 *Physical Properties*

Physical properties of the DVR soils that would be of interest in determining an application rate for treated wastewater include texture, percent coarse fragments (gravel, cobbles), depth to a restrictive layer, and depth to evidence of groundwater.

Pursuant to laboratory analysis results, dominant soil textures for the DVR are loamy sand, sandy loam, and sand, in order of dominance. There was only one occurrence of a clayey soil. That soil texture occurred at sample location 8A2, which is located in Field 8 at a depth of 42 to 57 inches below ground surface. The texture is a clay loam, which is a layer of accumulation of clay; however, it does not contain a high enough clay content to meet the criteria as a restrictive layer for infiltration of surface water (irrigation water). The loamy sands, sandy loams and sand that dominate the site are highly conducive to managed agricultural irrigation and cropping practices. These soil textures are also very conducive to either sprinkler or surface irrigation practices.

Evidence of depth to groundwater includes soil mottling and/or gleying. These conditions are described in the Recommended Fields Technical Memo, Appendix 1 and are therefore not repeated here. High groundwater areas were designated using soils sample location notes as well as DISTRICT groundwater monitoring data. There is potential for areas of high ground water to occur within Fields 5, 6, 7, 9 and 10 based on currently available data. It has been recommended to the DISTRICT, that additional investigation be conducted in those fields preliminarily identified as having potential for shallow groundwater to more accurately determine depth to groundwater.

# 2.2.4.2 *Chemical Properties*

The laboratory analysis conducted by AgSource Harris of the soils provides background levels of nutrients contained in the soils under a freshwater irrigation regime. This information is helpful to the DISTRICT in developing a nutrient balance for the Ranch using these background levels as an input of nutrients. The laboratory analysis indicated the DVR soils are in the "normal" range for background levels of nutrients and constituents. There are no significantly high levels of nutrients/constituents and no significantly low levels of soil nutrients/constituents that would affect a nutrient balance for the DVR. Please see Appendix 3.

There is one instance (one sample) that showed an elevated Buffering Capacity, which occurs in Field 1. Given that this is one location across the Ranch, this instance is not deemed significant. The AgSource Harris data contained in Appendix 3 provides nutrient management guidelines for production of pasture grass. These guidelines hold true whether the crop is harvested or grazed in place.

# 2.2.5 Livestock Grazing

Currently the DVR is grazed in the late spring through early fall by approximately 1000 head of cattle under a grazing permit with the DISTRICT. Although the DISTRICT Pasture (see Figure 1 and DP on laboratory results) has not been subject to consistent grazing over the last seven years, chemical properties are not significantly different as compared to the areas of the Ranch that have been consistently grazed.

Wood Rodgers professional opinion is that the level of grazing which is occurring on the DVR is moderate, dispersed, and managed based on availability of feed. Thus, under this management regime no one area or field would be impacted by the production of manure and associated input of nutrients under a freshwater irrigation regime. Under a recycled water regime there would be a small excess of nitrogen available (Table 5, Appendix 1, Grazing Options tech Memo). Conversely, if the cattle were managed to remove 90 percent of the available feed in any field before being rotated to the next field, cattle use would be concentrated, and an elevation in the levels of available nitrate would be expected.

If cattle grazing is to continue within the irrigation/reuse fields, it is recommended that the carrying capacity of the crop be determined and livestock use be limited to a moderate level on a rotation system. Carrying capacity is defined as the maximum stocking rate possible that is consistent with maintaining or improving vegetation or related resources. It may vary from year to year on the same area due to fluctuating forage production. The field could be drug with a tractor and harrow between use periods to break up the "cow pies" allowing them to dry and disperse. Please see the Grazing Options Technical Memo, Appendix 1 for additional information.

#### 2.2.6 Vegetation

Existing vegetation on the Diamond Valley Ranch consists of pasture grass species. The wetter portions of the ranch support grass-likes such as Baltic rush and sedges. When reviewing soil physical and chemical characteristics with the vegetation the Ranch is currently supporting, there are no unique vegetation species or communities. In other words, the species that occur are what is expected for mountain meadow community types, and are closely tied to soil moisture conditions rather than soil texture and soil chemical properties.

An important consideration in developing an NMP is to maximize nutrient uptake by the vegetation. Alfalfa and pasture grass were examined as crop alternatives for the Diamond Valley Ranch reuse area specifically for nutrient uptake calculations.

In addition, a Technical Memo was developed for use by the DISTRICT that explored alternative crops. Please see Appendix 1. Technical Memo recommendations were as follows:

- The DISTRICT consider a mix of crop uses (hay, crop, and wetlands mitigation plant materials). This would allow the DVR a variety of revenue opportunities as well as opportunity to maximize nutrient uptake and effluent reuse.
- Another viable option would be to practice hay production for harvest or grazing, or both. One cutting could be harvested due to short growing season from pasture hay fields, followed by grazing on irrigated stubble of that crop.
- The DVR Nutrient Management Plan should consider crop/plant alternative opportunities for nutrient uptake for the crops as determined by the DISTRICT. Nutrient uptake would be considered as a nutrient loss in the nutrient balance of the ranch under the effluent irrigation scenario. This analysis will provide the DISTRICT with information to be able to determine the crops they want to consider for production and maximize nutrient uptake and effluent reuse.
- Wetland sod may still be an alternative; however, citations for the nutrient uptake of species that would grow in a non-open water situation were not available. If this were to be considered as an alternative, tissue samples would need to be collected on a current wastewater wetland site and compared to tissue samples of a natural site.

#### 2.2.7 Surface Water

The West Fork of the Carson River, located north of the Diamond Valley Ranch, provides fresh water irrigation to the Ranch. Flows from Indian Creek are transported along the southern boundary of the Ranch in the IC Flood Control channel and in Indian Creek. Figure 4 shows the location of the West Fork of the Carson River, creeks, and the irrigation ditches in relation to the Diamond Valley Ranch property.

#### 2.2.7.1 Water Rights

Water rights for the Carson River are administered per the Alpine Decree. The reach of the West Fork of the Carson River from the gage at Woodfords to the California/Nevada state line has a rotating weekly water supply during the irrigation season. As long as an adequate water supply is available for all water-righted lands, the priority of the water right is of no consequence. However, when quantities are not available to supply all water- righted lands with their full rights, the priority of the water right is considered. The priority of a given water right has been established based upon the date of first use.

The DISTRICT holds surface water rights to the West Fork of the Carson River and Indian Creek. These water rights provide irrigation flows to the Diamond Valley Ranch via a number of ditches. Figure 4 displays the West Fork of the Carson River and Indian Creek water rights held by the Diamond Valley Ranch and surrounding properties.

#### 2.2.8 Ground Water

Monitoring well locations were identified by the DISTRICT (Figure 2). The average groundwater depths in the existing monitoring wells and average water quality for selected parameters for the period from October 1988-August 2007 are listed in Table 4 below. The DVR has potential for shallow depth to groundwater in several locations. It has been recommended that further investigation be conducted to more accurately determine depth to groundwater in these areas.

| Well            | Depth to<br>groundwater<br>(ft btoc) | NO3-N<br>(mg/l) | Total N<br>(mg/l) | Total P<br>(mg/l) | TDS (mg/l) |
|-----------------|--------------------------------------|-----------------|-------------------|-------------------|------------|
| ACMW-01AW       | 6.99                                 | 0.51            | 0.56              | 0.05              | 85.6       |
| (Main Dam)      | 0.77                                 | 0.01            | 0.00              | 0.00              | 00.0       |
| ACMW-01BE       | 10.35                                | 0.34            | 0.50              | 0.03              | 83.5       |
| (Secondary Dam) |                                      |                 |                   |                   |            |
| ACMW-02N        | 6.71                                 | 0.10            | 0.20              | 0.02              | 94.5       |
| (Access Gate)   |                                      |                 |                   |                   |            |
| ACMW-02S        | 6.98                                 | 0.13            | 0.24              | 0.02              | 76.9       |
| (Access Gate)   |                                      |                 |                   |                   |            |

Table 4. Groundwater Quality Data, 1988-2007 (DISTRICT)

Note: Total nitrogen data from Oct 1988-Nov 2001.

# 3.0 RECYCLED WATER IRRIGATION PLANNING

This section of the Diamond Valley Ranch NMP is intended to present the foundation for evaluating the hydraulic loading limit for the Diamond Valley Ranch pursuant to the guidance used to develop this NMP.

Wood Rodgers prepared an Irrigation Methods Technical Memo (Appendix 1) that included an evaluation of an array of irrigation methods that the DISTRICT can consider for future management of the recommending that the Diamond Valley Ranch. In addition, Wood Rodgers evaluated typical surface and aerial irrigation methods to determine hydraulic loading rates under a recycled wastewater irrigation regime.

As previously stated, the primary intent of this NMP is to maximize nutrient uptake. Surface and spray irrigation were examined as irrigation method options for the Diamond Valley Ranch reuse area, per the recommendation of the Irrigation Methods Technical Memo.

# 3.1 C-Line Delivery System

Recycled water is currently delivered to Harvey Place Reservoir for agricultural irrigation purposes. Recycled water is delivered to the reservoir year-round. The 28-year average flow rate, per the DISTRICT, is 4.5 MGD. Modifications to the C-Line will need to be made to deliver recycled water to DVR.

# 3.2 Irrigation System

Irrigation would typically occur between April 1 and October 15. For this NMP, Harvey Place Reservoir is assumed to be the source of the recycled irrigation water and infrastructure upgrades will be needed to convey the recycled water to the proposed fields for irrigation.

If the DISTRICT were to select an aerial irrigation method, engineered design of fields and the conveyance and field delivery systems would be required. Selection of an aerial application system would result in greater initial capital investment.

Technical Memo recommendations were as follows:

- It is Wood Rodgers opinion that the type of irrigation method chosen should be dependent on the type of crop to be grown, capital budget for initial materials costs, operating budget for pumping if required, and labor if needed by the system.
- The Diamond Valley Ranch should consider a type of surface irrigation and a type of aerial irrigation to determine hydraulic loading rates.

# 3.2.1 DVR Irrigation System

Surface irrigation and spray irrigation were examined as potential alternatives. Surface irrigation provides the highest benefit based upon maximizing recycled water use. Please see Section 5.0 Hydraulic Loading.

# 3.2.2 Storage

Recycled water is currently stored in Harvey Place Reservoir with a capacity of 3,800 acft.

# 3.3 Irrigable Areas

Wood Rodgers prepared a Recommended Fields Technical Memo that determined that the Diamond Valley Ranch has approximately 904 irrigable acres. Please see Appendix 1 and Section 2.2.1.

# 3.4 **Operating Procedures**

Following are typical procedures that are presented as a template for the DISTRICT and Lahontan to build on for recycled water reuse at the Diamond Valley Ranch. They are written from the perspective of a surface irrigation system. However, they are also applicable to irrigation with an aerial application method.

# 3.4.1 Coordination to Initiate Irrigation

Typically, recycled water is released for irrigation as the crop needs arise. A typical procedure using existing guidelines used to develop the DVR NMP is as follows:

- 1. Take initial readings for volume calculations.
- 2. Identify where recycled water will be released, start date and time, approximate irrigation duration.
- 3. Release recycled water.
- 4. Confirm when recycled water supply should be closed off.
- 5. Shut off flow and take final readings for volume calculations.
- 6. Check irrigation ensuring tailwater management.

# 3.4.2 Reuse Irrigation

The following outlines typical steps for irrigation with recycled water:

- 1. Diamond Valley Ranch fields have been primarily irrigated with West Fork Carson River Water. The Ranch intends to transition to recycled water.
- 2. Determine proposed irrigation schedule and determine that the schedule will not interfere with Ranch management/crop production.
- 3. Open valves releasing water to appropriate sites. Read/record water flow meters prior to and immediately following completion of irrigation.
- 4. Fields can be irrigated on a schedule depending on season, precipitation, and air temperature.
- 5. Tailwater containment is initiated by closing check gates located at field boundaries to irrigate downhill fields with any tailwater.

# 3.4.3 Tracking

The DISTRICT will be required to track the quantity of recycled irrigation water applied to each irrigation area.

The DISTRICT will be required to record total volume released for irrigation.

The DISTRICT will create a log to track the irrigation within each irrigation area. The log will indicate the date, area irrigated, irrigated acreage, start time, stop time, amount of water used, and any comments.

## 3.4.4 Tailwater Management

The DISTRICT will apply recycled water for agricultural irrigation purposes inclusive of tailwater management. The following procedures will be used to manage tailwater when irrigating with recycled water:

- 1. Attend irrigation of fields and stop flow as water advances toward the end of the field to manage tailwater.
- 2. In the event that tailwater is generated, containment can be accomplished by two methods, depending on the location of the field. Water can be conveyed by ditch or pipe and released for irrigation on a downstream field, or water can be contained by closing check gates and impounding the water in the containment area.
- 3. A tailwater containment area will be located on the property (size and location to be determined).

# 3.4.5 Tailwater Return

The DISTRICT will use the recycled water for agricultural purposes with tailwater management to ensure no discharge to surface water systems. The following procedures will be used to contain tailwater, if generated from the project site when irrigating with recycled water:

- 1. Irrigation will be managed to optimize irrigation efficiency. Personnel will attend irrigation of the fields to ensure that flows are stopped when irrigation demands have been met to avoid tailwater generation from the fields.
- 2. Fields may be designed so that tailwater from upper fields flows onto lower fields as irrigation.
- 3. All tailwater reaching the low end of the project area will flow into a tailwater recovery area with a capacity to be determined to prevent any surface discharge from the site when irrigating with recycled water.

#### 3.4.6 Winter Operation

Recycled water will be stored in Harvey Place Reservoir until it is needed at the beginning of the irrigation season. As such, winter irrigation will not be authorized. Emergency disposal of recycled wastewater from HPR to the DVR may be authorized if approved by Lahontan.

# 4.0 CROP MANAGEMENT PLAN

# 4.1 Crops

Wood Rodgers prepared a Crop/Plant Selection Technical Memo (Appendix 1) recommending that the DISTRICT consider a mix of crop uses (hay, crop, and wetlands mitigation plant materials) in order to allow the DVR a variety of revenue opportunities as well as opportunity to maximize nutrient uptake and recycled water reuse. Another viable option recommended in the Crop/Plant Selection Technical memo was to practice hay production for harvest. It is presently assumed that one cutting could be harvested due to short growing season from pasture hay fields.

Final crop selection will be dependent on growing season in the study area, availability of supplemental irrigation, the quality of the domestic wastewater with respect to the salinity tolerance of the crop, and market if the DISTRICT determines that it is beneficial to produce a cash crop.

In turn, the crop(s) selected will be used to determine the hydraulic loading limit and water balance calculations. The hydraulic loading limit can be largely influenced by the potential of the crop to uptake nutrients, primarily nitrate. The water balance is primarily based on the need of the crop or the evapotranspiration rates and soil permeability rates. Nutrient uptake is considered as a nutrient loss in the nutrient balance of the ranch under the recycled water irrigation scenario. (Please see the Grazing Options Technical Memo, Appendix 1).

# 4.1.1 Crop Selection

Potential forage crops selected for wastewater application modeling in this NMP included alfalfa and pasture grass. These crops are appropriate for this planning application as they are adapted to the local climatic and soil conditions, a market exists for sales, and they are grown on the DVR (pasture grass) and nearby ranches (alfalfa). In addition, the majority of source information available for determining hydraulic loading limit uses alfalfa as the crop. Flax, soybeans, and sunflowers were not considered at this time, since a market analysis would need to be completed to determine if production would be of benefit to the DISTRICT.

# 4.1.2 Evapotranspiration Rates

Evapotranspiration (ET) rates are used as water losses in hydraulic loading limit and water balance calculations. Values for average monthly ET were obtained from WRCC (2008) for measurements made at Markleeville, California, for the period 1998-2008. The data are summarized in Table 5. Please see Appendix 2, Table 1 for supplemental climate data.

| Month         | Average ET (in) |
|---------------|-----------------|
| January       | 1.44            |
| February      | 1.82            |
| March         | 3.76            |
| April         | 4.66            |
| May           | 7.22            |
| June          | 8.56            |
| July          | 9.05            |
| August        | 8.63            |
| September     | 8.51            |
| October       | 3.86            |
| November      | 1.81            |
| December      | 1.27            |
| Annual total= | 57.89           |

 Table 5. Monthly Average ET for Markleeville, CA (WRCC 2008)

## 4.1.3 Nutrient Uptake

A primary concern with recycled water application for agricultural irrigation purposes is maintaining ground water quality. In order to prevent nitrogen from leaching to groundwater, nitrogen uptake by plant species is used as a factor in computing hydraulic loading based on nitrogen as the limiting factor. Plants will uptake nitrate, the soluble form of nitrogen that is present in recycled water.

Nitrogen uptake by alfalfa is well documented, and a value of 200 lb/ac/day is commonly used in hydraulic loading limit calculations (Metcalf and Eddy 1991). The value for nitrogen uptake by pasture grass, 80 lb/ac/day, was obtained from California Plant Health Association (2002).

# 4.1.4 Soil Salinity Tolerated by Crop

Soil salinity tolerated by a specific crop is used for determining the leaching fraction in calculating irrigation water requirements. The assumption is that excessive salinity causes a decrease in crop production.

The soil salinity tolerance value for alfalfa (2 mmhos/cm) was obtained from Metcalf and Eddy (1991) and USDA (1992). The soil salinity tolerance value for pasture grass (3.1 mmhos/cm) was obtained from USDA (1992).

# 4.1.5 Other Variables

Additional Variables are considered when determining the irrigation requirements/consumptive use of crops. These are discussed following.

# 4.1.5.1 Precipitation

An estimate of monthly hydraulic loading is determined by considering the partial contribution of nutrients by estimating recycled domestic wastewater demand. Recycled wastewater irrigation is considered supplemental to natural precipitation. Average monthly values for total precipitation obtained from WRCC (2008) for

measurements made at Markleeville, California, for the period 1909-2004 are summarized in Table 6. Please see Appendix 2, Table 2 for supplemental information.

| Month         | Average P (in) |
|---------------|----------------|
| January       | 3.72           |
| February      | 3.14           |
| March         | 2.10           |
| April         | 1.29           |
| May           | 0.99           |
| June          | 0.60           |
| July          | 0.39           |
| August        | 0.46           |
| September     | 0.47           |
| October       | 0.93           |
| November      | 2.11           |
| December      | 3.01           |
| Annual total= | 19.20          |

 Table 6. Monthly Average Total Precipitation for Markleeville, CA (WRCC 2008)

# 4.1.5.2 Irrigation Method Efficiency

Irrigation efficiency varies with the method chosen for distribution. For the initial development of this NMP, surface (flood/furrow) irrigation and spray irrigation (hand/wheel lines or center-pivot sprinklers) were analyzed. The efficiency rates are listed in Table 7 (Metcalf and Eddy 1991).

| Table 7. Inigation Efficiency (Metcan and Eddy 1991) |                |  |  |
|------------------------------------------------------|----------------|--|--|
| Irrigation Method                                    | Efficiency (%) |  |  |
| Surface                                              | 65             |  |  |
| Spray                                                | 70             |  |  |

#### Table 7. Irrigation Efficiency (Metcalf and Eddy 1991)

#### 4.1.6 Limiting Factor Determination

The hydraulic loading rates based on irrigation water, nitrogen limits, and soil permeability were calculated for the following four combinations:

- alfalfa/surface
- alfalfa/spray
- pasture grass/surface, and
- pasture grass/spray.

There were three loading rates (consumption, nitrogen, and permeability) calculated for each of the four combinations listed above. The comparison of the three hydraulic loading rates ensures that the quantity of recycled water applied to the crops will adequately fulfill specific crop requirements, safely percolate through the soil profile, and protect groundwater. In comparing these hydraulic loading rates, the lowest value of the three (maximum allowable application rate of recycled water) is the primary limiting factor. Please see Section 5.0 Hydraulic Loading for more in-depth discussion.

# 4.2 Nutrient Balance Comparison

Groundwater samples should be collected from existing and new monitoring wells that will be located at various distances down gradient from the fields that are proposed to be irrigated with recycled water. The nitrate concentration in the groundwater should be monitored quarterly and compared to the previous year's data. The drinking water standard (regulatory threshold) for nitrate is 10 mg/l, however the DISTRICT feels that it is prudent to monitor for a "red-flag" threshold level of 7 mg/l, as suggested in "WTS-1B: General Criteria for Preparing an Effluent Management Plan," prepared by the Nevada Department of Environmental Protection (NDEP). This will allow for alternative management opportunities prior to reaching the regulatory threshold. The DISTRICT understands that State Water Boards may impose a more stringent trigger value if an additional factor of safety is desired.

# 5.0 HYDRAULIC LOADING

Application of recycled water will vary with seasonal demands of the crop. During the non-irrigation season, recycled water irrigation will not occur and it will be stored in Harvey Place Reservoir. During the irrigation season, recycled water irrigation will be used to meet the requirements of the crops. The DISTRICT will control the recycled water application rates. Monthly recycled water irrigation totals will be recorded by the DISTRICT.

Allowable hydraulic loading for irrigation with recycled water must be evaluated based on irrigation water requirements, nitrogen uptake rates for crops, and soil permeability. Given the fact that the DVR is not irrigated with recycled wastewater, hydraulic loading rates were calculated (estimated) per the methods outlined in Metcalf and Eddy (1991) for use later when comparing to current year and past year site-specific loading rates as described in Section 4.2.

# 5.1 Estimating a Hydraulic Loading Rate

To provide an estimate of hydraulic loading rates for the DVR, three distinct irrigation balances were calculated for each crop/irrigation combination for the reuse site. For each combination listed above under Section 4.1.6, the first two balances—plant consumptive use needs and nitrogen loading limit—are prepared to determine the optimal recycled water application rate for the crops per the chosen method of irrigation and protect groundwater quality. The third evaluation for each combination considers the effect of soil permeability at the site, and is used for design purposes to help insure that the site is appropriate for recycled water irrigation and ponding and runoff will not occur.

Depending upon site-specific factors, such as the recycled water nitrogen content and the plant crop's nitrogen uptake rate, one of the first two balances (consumptive use or nitrogen loading) will govern for groundwater protection.

|         |            | Ka<br>Hydr  | Irrigation<br>Application<br>Rate<br>ac-ft/Ac |              |      |
|---------|------------|-------------|-----------------------------------------------|--------------|------|
| Crop    | Irrigation | Consumptive | Nitrogen                                      | Soil         |      |
|         |            | Use         | Loading                                       | Permeability |      |
| Alfalfa | Surface    | 71.89       | 86.05                                         | 274.72       | 5.99 |
| Alfalfa | Spray      | 66.75       | 86.05                                         | 274.72       | 5.57 |
| Pasture | Surface    | 70.49       | 36.33                                         | 274.72       | 3.03 |
| grass   |            |             |                                               |              |      |
| Pasture | Spray      | 65.45       | 38.20                                         | 274.72       | 3.18 |
| grass   |            |             |                                               |              |      |

# Table 8. Summary of Calculated Hydraulic Loading Rates and Irrigation ApplicationRate

Interpretation of the results presented in Table 8 is as follows:

The lowest number in a given row (**bolded**, **36.33**) is the maximum hydraulic loading rate for the given crop/irrigation combination; the highest value of the collected minima from all rows will identify the best crop/irrigation combination (*bolded/italics*, **71.89**). For example, the allowable loading for alfalfa/surface irrigation is 71.89 in/yr, the allowable loading for alfalfa/spray is 66.75 in/yr, the allowable loading for pasture grass/surface irrigation is 36.33 in/yr and the allowable loading for pasture grass/spray is 38.20 in/yr (because the pasture grass does not have the nitrogen-fixing capability of alfalfa). From these numbers, 71.89 in/yr is the greatest, and alfalfa/surface irrigation presents the best possible combination since the goal is to maximize recycled water use.

The limiting rate calculated for the alfalfa/surface irrigation combination (71.89 in/yr) is the irrigation water requirement (consumptive use). Equations are included in Sections 5.2 through 5.4, and full calculations are in included in Appendix 2 (Tables 4 through 15).

For the combination of alfalfa/surface irrigation, the maximum annual nitrogen hydraulic loading rate will be:

## 71.89 in/yr 5,416 ac-ft/904 irrigable ac (5.99 ac-ft/ac) 1.95 Mgal/ac

The above calculations were based on the assumption that there are no additional inputs of nitrogen being added to the crop as fertilizer.

Table 9 presents an example of calculating the hydraulic loading for nitrogen with the necessary steps for the calculations identified following.

| Month | Irrigation<br>Monthly<br>Flow | Irrigation<br>Monthly<br>Flow | Irrigated<br>Area | Irrigation<br>Monthly<br>Flow | Monthly<br>Avg<br>Total<br>Nitrogen<br>in<br>Effluent | Factor for<br>volatilization,<br>mineralization,<br>leaching | Available<br>Nitrogen<br>in<br>recycled<br>water | Fertilizer | Total<br>Available<br>nitrogen<br>applied | Cumulative<br>Nitrogen<br>Applied to<br>Date | % Annual<br>Nitrogen |

| Nov   | 0                             | 0                             | -                 | _                             | -                                                     | -                                                            | -                                                | -          | -                                         | 200                                          | 100.0                |
| Dec   | 0                             | 0                             | -                 | -                             | -                                                     | -                                                            | -                                                | -          | -                                         | 200                                          | 100.0                |
| Total | 1640                          | 5032                          | 904               | 5.57                          | 17.6                                                  | 0.25                                                         | 200                                              | 0          | 200                                       | 200                                          | 100.0                |

#### Table 9. Example Nitrogen Load Calculation

Notes: Average 4.5 MGD x 365d/yr = 1642.5 Mgal/yr [use 1640 Mgal for calculation purposes]

Monthly flow (Q1) = 1640 Mgal/yr x yr/8mo irrigation = 205 Mgal/mo

Monthly flow (Q2) = 205 Mgal/mo x 1cf/7.48 gal x 1ac-ft/43560cf = 629ac-ft/mo

Irrigated Area (A) = 904 ac irrigable [Wood Rodgers Tech Memo]

Monthly Average Total N (Cn) = 17.6 mg/l [DISTRICT]

Fraction of Nitrogen Lost (f) = 0.20 from denitrification and volatilization [Metcalf and Eddy 1991] + 0.05 lost to leaching

[Wood Rodgers calculations, DVR NMP] = 0.25

Available N in effluent (Neff) = 205 Mgal/mo x 17.6 mg/l x 3.79 l/gal x 1g/1000mg x 1lb/454g x (1-0.25) / 904 ac = 25 lb/ac/mo

% Annual N = 100 x Ncum / 200 lb/ac/yr for alfalfa

Example calculated assuming that the alfalfa/ surface irrigation combination is selected and all 904 of the irrigable acres are used, entire volume of recycled water from treatment plant for the year is used over the 8mo irrigation season, and no additional fertilizer is applied. f = 0.2 and U = 200 lb/ac/yr from Metcalf and Eddy (1991). 5.57ac-ft/ac = 66.80 in/yr for 904ac. This value is less than the maximum calculated hydraulic loading rate of 71.89 in/yr.

- 1. Calculate "actual nitrogen loading" applied on a monthly basis from volume of recycled water applied, concentration of total nitrogen in recycled water used for irrigation, and factors accounting for nitrogen available for plant uptake. Nitrogen available from recycled water is based on a 20% loss to volatilization/denitrification and a 5% loss to leaching (ref hydraulic loading spreadsheets in the appendix) for a total loss of 25%.
- 2. Include any nitrogen added as commercial fertilizer to determine the "actual nitrogen loading." (Wood Rodgers recommends against application of nitrogen-containing commercial fertilizer since doing so would reduce the amount of recycled water that can be applied for irrigation).
- 3. Calculate "cumulative annual nitrogen loading" each month as the sum of the monthly "actual nitrogen loading" from the beginning of the year through each quarter.
- 4. The "allowable nitrogen loading" is the annual nitrogen uptake rate for the crop grown on the irrigated fields. Compare available nitrogen applied to the annual uptake rate by calculating the percentage on a monthly basis: monthly "cumulative annual nitrogen loading" divided by "allowable nitrogen loading."

# 5.2 Grazing

Wood Rodgers prepared a Grazing Options Technical Memo (Appendix 1) in order to determine if livestock grazing nutrient inputs from manure would have an impact on the nutrient balance for the DVR under a treated effluent irrigation regime. This information will be useful to the DISTRICT in their decision-making process on whether to continue livestock grazing under a treated effluent irrigation regime.

The Grazing Options Technical Memo recommended that manure be analyzed at a statically accurate level to provide precise nutrient inputs before a decision is made regarding livestock grazing.

The initial results of the grazing analyses indicated that the grazing coupled with recycled water irrigation would result in an excess of nitrogen due to the input from manure. Although livestock grazing removes nutrients from the ranch through harvesting of the crop, it continues to provide nutrient input to the system from manure. As a result, this NMP assumed no grazing for calculating the hydraulic loading rates as reported above in Section 5.0.

# 5.3 Recycled Domestic Wastewater

Recycled water typically contains high levels of mineral salt concentrations. This constituent can affect plant growth, soil permeability and ground water quality. In addition, recycled water contains a biological component that has health implications based on degree of human contact. The DISTRICT laboratory provided domestic wastewater quality data for the treatment plant at South Lake Tahoe, California, from 1980-2007 (key parameters were summarized in Table 1, Section 2.2.3 Recycled Water Quality, and for Harvey Place Reservoir in Alpine County, California, from 1989-2007 (key parameters summarized in Table 2, Section 2.2.3.

The data provides a basis for a conservative estimate for recycled water application rates. Physical, chemical, and biological wastewater constituents evaluated include electrical conductivity (EC), suspended solids (SS), ammonia, nitrate, total phosphorus, chloride, total dissolved solids (TDS), and total Kjeldahl nitrogen (TKN–organic nitrogen plus ammonia nitrogen), chemical oxygen demand (COD), biochemical oxygen demand (BOD), and coliforms (total and fecal). Full data tables, as provided by the DISTRICT, are included in Appendix 2, Tables 2 and 3. TDS, EC, and nitrogen parameters are used in developing hydraulic loading limits. TDS and EC are parameters used to describe the concentration of salts in the applied wastewater.

From a health and regulatory perspective, the level of fecal coliform is of primary concern. This component of the applied recycled wastewater is given in MPN/100ml (most probable number). Existing guidance from Nevada does not require a buffer zone for spray or surface irrigation at values less than or equal to 2.2 MPN, but public access must be limited.

# 5.4 Irrigation Requirements – Hydraulic Loading Based on Consumptive Use

The equation for hydraulic loading based on irrigation requirements as the limiting factor (Metcalf and Eddy 1991) is:

$$R = \frac{ET - P}{1 - LR / 100} \tag{1}$$

Where R

R= net irrigation requirement, inET= crop evapotranspiration, in

*P* = precipitation, in

*LR* = leaching requirement, %

Arid climates require leaching of salts from the soil profile to control salinity in the crop root zone. The leaching requirement is calculated from the following equation (USDA 1992):

$$LR = \frac{EC_w}{5EC_e - EC_w} \tag{2}$$

Where *LR* = leaching requirement, %

 $EC_w$  = salinity of applied recycled water (mmhos/cm)

 $EC_e$  = soil salinity tolerance of crop (mmhos/cm)

A depth of water (D) greater than the net irrigation water requirement (R) calculated from equation 1 must be applied to the irrigated area in order to ensure that it receives the net irrigation water requirement. This is due to water loss during application and the fact that a distribution system is unable to apply water uniformly over the entire irrigated area. The total irrigation requirement is this depth of water (D), and it is calculated from the following equation (Metcalf and Eddy 1991):

$$D = \frac{R}{E_{\mu}/100} \tag{3}$$

Where *D* = total irrigation requirement, in

*R* = net irrigation requirement, in

 $E_u$  = unit application efficiency for distribution system, %

The irrigation water budget is based on the selected crop, irrigation method, and irrigation interval.

# 5.5 Nitrogen Balance - Hydraulic Loading Based on Nitrogen

The equation for hydraulic loading based on nitrogen as the limiting factor (Metcalf and Eddy 1991) is:

$$L_{w(n)} = \frac{(C_p)(P - ET) + (4.4U)}{(1 - f)(C_n - C_p)}$$
(4)

Where 
$$L_{w(n)}$$
= allowable hydraulic-loading based on nitrogen loading rate, in/yr $C_p$ = total nitrogen in percolating water, mg/L $P$ = design precipitation rate, in/yr $ET$ = design evapotranspiration rate by crop, in/yr $U$ = nitrogen uptake by crop, lb/ac-yr $4.4$ = combined conversion factor $f$ = fraction of applied total nitrogen removed by denitrification and volatilization $C_n$ = total nitrogen in applied wastewater, mg/L

Potential nitrogen contamination of groundwater is a major concern with recycled water application. Recycled water is naturally rich in nutrients and supplies these nutrients to the crops. The above equation balances the crop utilization of nitrogen with the nitrogen concentration of the recycled water and the fraction of applied total nitrogen that is removed by denitrification and volatilization.

In order to determine the hydraulic loading based on nitrogen, Wood Rodgers consulted "WTS-1B: General Criteria for Preparing an Effluent Management Plan," prepared by the Nevada Department of Environmental Protection (NDEP). Wood Rodgers set a conservative "red-flag" threshold level of 7 mg/l for  $C_p$ , as is common practice in developing a Nevada Effluent Management Plan (EMP). This was done to insure that the receiving groundwater resource will not be excessively degraded to a point where it is no longer useable (please also refer to the Assimilation Capacity Technical Report, Appendix 4). The DISTRICT understands that State Water Boards may impose a more stringent trigger value if an additional factor of safety is desired.

# 5.6 Soil Permeability - Hydraulic Loading Based on Soils

The equation for hydraulic loading based on soil permeability as the limiting factor (Metcalf and Eddy 1991) is:

 $L_{w(p)} = ET - P + W_p$ (5) Where  $L_{w(p)}$  = wastewater hydraulic-loading rate based on soil permeability, in/mo ET = design evapotranspiration rate, in/mo P = design precipitation rate, in/mo  $W_p$  = design percolation rate, in/mo

The design percolation rate  $(W_p)$  based on soil permeability was assumed to be 4% of the minimum soil permeability (Metcalf and Eddy 1991). This equation determines the allowable limits of a soil to transmit percolating water below the rooting zone to groundwater. Prevention time of nitrate migration to groundwater is of utmost importance; therefore, limits imposed by nitrogen will take precedence.

# 6.0 ASSIMILATIVE CAPACITY

Lahontan informed the DISTRICT that an Assimilative Capacity Model must be completed as an element of the NMP. At the direction of the DISTRICT, Wood Rodgers calculated an assimilative capacity for the receiving waters of the DVR and prepared a brief Assimilation Capacity Technical Report. Please see Appendix 4.

The Technical Report initially analyzed water quality data from sites in Carson Valley, Nevada, that have been using recycled water for irrigation. The intent was to determine whether a degradation of the groundwater was occurring because of the recycled water irrigation. This method was the best available given the availability of site-specific data. A predictive model, developed from various assumptions, would not provide the same level of confidence as the actual site data.

The type of predictive model requested by Lahontan could not be developed, as there was no evident trend correlating the concentration of nitrate in the receiving groundwater to the concentration of total nitrogen in the applied recycled water that was observed at the Carson Valley locations.

Wood Rodgers proceeded in developing the DVR NMP using the methods required by NDEP (outlined in "WTS-1B: General Criteria for Preparing an Effluent Management Plan") to determine the maximum amount of recycled water that could be applied as agricultural irrigation. The process is described in Section 5.0 Hydraulic Loading.

As stated in the Technical Report, Wood Rodgers believes that the "nitrogen loading" determination (Metcalf and Eddy 1991) accomplishes the same goal as an assimilation capacity model, but in a different manner. The Metcalf and Eddy method allows for precise determination of the amount of recycled water that can be applied, given the nitrogen concentration of the recycled water, the threshold nitrate concentration for the receiving water, the specific crop (alfalfa fixes nitrogen and more recycled water can be applied compared to pasture grass), and the climate conditions (evapotranspiration and precipitation).

Because no cumulative effect (nitrogen loading) was observed in the recorded NDEP data, Wood Rodgers concluded that the assimilative capacity of receiving waters will not be impacted when irrigating with high-quality recycled water such as that produced by the South Tahoe WWTP and a predictive degradation model is not necessary. The accepted practice of using the three distinct irrigation balances to determine the limiting hydraulic loading rate is adequate because of the "nitrogen loading" determination, which allows the reuser to set the threshold and calculate the total amount of recycled water that could be applied before theoretically reaching that specified threshold number.

In the case of this specific NMP for the Diamond Valley Ranch, the recommended application rate is significantly less than the application rate calculated based on nitrogen loading.

Wood Rodgers' professional opinion is that the only way to absolutely observe the presence or absence of cumulative effects is to determine the existing (pre-irrigation) baseline concentrations of nutrients in the groundwater (which the DISTRICT has already collected), begin irrigating, monitor the groundwater for specific nutrients, and compare post-irrigation concentrations to pre-irrigation concentrations to determine if a trend exists. Continued monitoring while irrigating with recycled water will allow the DISTRICT a means to track the site-specific effects and modify their irrigation management/ranch management plan as needed.

# 7.0 RELEASE PREVENTION AND PUBLIC PROTECTION

The following is presented as existing guidelines that the DISTRICT may wish to use as a foundation from which to build site-specific guidance for the Diamond Valley Ranch. These guidelines are also applicable to an aerial irrigation system.

# 7.1 Release Prevention

Recycled water must be applied in a manner to minimize any potential impacts to groundwater quality. The following summary describes the specific measures that will be taken to minimize the potential for surface release from the reuse site and preserve groundwater quality.

# 7.1.1 Standing Water

Unnecessary ponding of recycled water should be avoided. In order to prevent unnecessary standing water, it is imperative that the irrigation system and tailwater recovery be operated properly. Standing water may be minimized through the following means:

- 1. Control of irrigation to prevent excessive tailwater
- 2. Use of laser leveled border strips irrigation
- 3. Manual control of pasture valves
- 4. Presence of an on-site irrigator monitoring surface irrigation progress
- 5. Maintenance of perimeter ditches and tailwater containment area

# 7.1.2 Tailwater Recovery

A tailwater recovery and return area may need to be constructed on the property. This area will contain any excess recycled water.

# 7.1.3 Unstable Ground Conditions

The irrigation system will be operated to minimize potential surface runoff by considering ground conditions before irrigating. Unsuitable conditions include frozen, saturated, or flooded soils. Fields will not be irrigated during or immediately following significant precipitation events.

# 7.14 Irrigation System Malfunction

DVR personnel will inspect the irrigated areas to ensure the irrigation system is operational. Any problems identified will be addressed and all necessary repairs will be completed promptly.

# 7.2 Spill Response

Spill response may be required in the event of bypass or failure of check gate structures, breach of irrigation ditches, or breach of containment berms. Spill response will entail the following:

- 1. Shut down irrigation
- 2. Close check gates to retain irrigation on upstream or downstream fields
- 3. Contain runoff and minimize any off-site discharge by diverting water with temporary ditches, impounding water at topographic low spots, and/or constructing containment berms

# 7.3 **Public Protection**

#### 7.3.1 Controlled Access

The DVR has a perimeter fence defining the property boundary and locked gates will restrict access to the reuse area.

## 7.3.2 Public Notification

The existing perimeter fence will be posted with "No Trespassing" and "Warning Recycled water Do Not Drink" signs. Notification signs will be placed at the access points and at minimum 500-foot intervals along the exterior fence line of application areas.

## 7.3.3 Worker Notification

DVR personnel directly involved with irrigating will receive training and notification regarding possible hazards and appropriate personal hygiene for working with recycled water.

Personal hygiene practices include:

- 1. Do not drink the irrigation water
- 2. Do not use the irrigation water for washing
- 3. Always wash hands and face with clean water and soap before eating or drinking
- 4. Wear rubber gloves when working on the irrigation system
- 5. Minimize skin contact with recycled water
- 6. Treat cuts immediately before continuing to work on the irrigation system
- 7. Report any problems that might pose a risk

# 8.0 MONITORING AND REPORTING

The DISTRICT will supply monitoring and reporting data to Lahontan in compliance with the Discharge Permit.

# 8.1 Monitoring

Monitoring associated with the DVR will be performed as required by the Discharge Permit. Suggested terms are as follows:

# 8.1.1 Recycled Water Volume

Monitoring of irrigation volume and rate of application will be performed through an automated metering device. DVR personnel will collect readings in order to determine the 30-day average flow.

## 8.1.2 Recycled Water Quality

Harvey Place Reservoir recycled water quality will continue to be monitored.

## 8.1.3 Groundwater

Groundwater quality will continue to be monitored at the existing monitoring wells. New monitoring wells may be added in the vicinities of the fields proposed for recycled water irrigation.

#### 8.1.4 Nitrogen Balances

A nitrogen balance will be calculated on an annual basis (Table 9). The annual balance will be compared to the initial calculation and the results of the previous year's balance, as well as the DVR groundwater "red-flag" threshold of 7 mg/l. The DISTRICT understands that State Water Boards may impose a more stringent trigger value if an additional factor of safety is desired.

# 8.2 Reporting

#### 8.2.1 Standard Reporting Procedures

Monitoring data will be provided monthly, quarterly, or annually as required by Lahontan and others.

#### 8.2.2 Emergency Reporting

Should an unauthorized discharge of recycled water occur, Lahontan shall be notified as soon as the release is identified. A written report on the release/discharge and the methods used for mitigation shall be submitted to Lahontan. The report shall list:

- 1. Date and time of discharge
- 2. Exact location and estimated amount of discharge
- 3. Flow path and bodies of water which the discharge reached
- 4. Specific causes of the discharge

5. Preventive and/or corrective actions taken

# 8.3 Sampling Protocol

## 8.3.1 Monitoring Wells

Sampling of the monitoring wells by the DISTRICT will follow the procedure outlined below.

- 1. Document sampling on field data sheet
- 2. Measure depth to groundwater from the top of casing
- 3. Remove approximately three well volumes with bailer or pump. Do not contaminate the well or samples if using a bailer. If a particular well is known to recharge slowly, pump well till casing is empty, allow well to refill then collect sample.
- 4. Obtain sample bottles with preservatives from the laboratory
- 5. Collect samples and immediately place them in a cooler

## 8.3.2 Recycled Water Sampling

Samples will be collected from Harvey Place Reservoir using containers, preservatives, and procedures recommended by the laboratory.

## 8.3.3 Flow Monitoring

Flow monitoring will be done with a flow meter. Daily and monthly readings will be recorded during irrigation. Readings may be collected manually or electronically. Location of daily irrigation applications will also be recorded to demonstrate appropriate distribution throughout the irrigation areas.

#### 8.3.4 Soils

Soil samples in irrigated areas will be collected and will be analyzed as required by Lahontan. Given the high quality of the South Tahoe WWTP effluent, it is recommended that soils be sampled every 3 to 5 years during recycled wastewater irrigation application.

#### 8.3.5 Vegetation

If the DISTRICT determines that it will be beneficial to produce a crop other than alfalfa, it is recommended that tissue samples be collected and analyzed annually to determine plant nutrient uptake specific to the DVR. A plant sample protocol would need to be developed in coordination with Lahontan if a crop other than alfalfa or pasture grass is grown.

| Projec | t Number:       | 8361.001 | Project Name: | STPUD NMP DVR                  |

### **Topic Introduction**

The South Tahoe Public Utility District (STPUD) is seeking guidance regarding crops that are regionally adapted, and grazed and/or harvested under effluent irrigation. The Diamond Valley Ranch (DVR) currently supports native pasture grasses maintained under fresh water irrigation and cattle grazing. Given the location and "short" growing season as a result of the mountain shadow and other influences relevant to the DVR, cool season plant species will suit it best. Cool-season plants are those that germinate and grow at lower temperatures of spring and fall and are not injured by light frost. Cool-season plants do not perform (grow) as well during periods of extended hot temperatures.

The science in brief:

Cool season plants and reduce (fix) CO2 directly by the enzyme ribulose bisphosphate carboxylase in the chloroplast. The reaction between CO2 and ribulose bisphophate, a phosphorylated 5-carbon sugar forms two molecules of a 3-carbon acid. This 3-carbon acid is called 3-phosphoglyceric acid and explains why the plants using this chemical reaction are called C3 plants. The 3-phosphoglyceric acid molecules move out of the chloroplast to the cytoplasm and are used to make hexose, sucrose and other compounds. The enzyme ribulose bisphosphate carboxylase also triggers a reaction where oxygen splits ribulose bisphophate into a 2-carbon acid and a 3-phosphoglyceric acid. The 2-carbon acid is respired to carbon dioxide and basically a loss to plant function. 15-40% of the light energy taken into the C3 plants is lost in this process called photorespiration. The percentage goes up in higher temperatures, so C3 plants use more available oxygen in cooler environments.

It is understood that the District may choose several plants/crops or mixture of pasture grasses to have in production at the same time. Thus, several options are presented for consideration.

### **Information Sought**

- 1. What crops/plants are adapted to this area under effluent irrigation?
- 2. What crops/plants can be grazed/and or harvested under effluent irrigation?
- 3. What crops/plants optimize nutrient uptake under effluent irrigation?

### Sources Investigated

(4) Constructing Wetlands in the Intermountain West: Guidelines for Land Managers. Univ. of Wyoming. 1999.

(5) Design Manual Constructed Wetlands and Aquatic Plant Systems for Municipal Wastewater Treatment. EPA/625/1-88/022. September 1988.

### Findings

#### 1. What crops/plants are adapted to this area under effluent irrigation?

The most common agricultural crops grown for revenue using waste water are corn (silage), alfalfa (silage, hay or pasture) forage grass (silage, hay or pasture), grain sorghum, and grains (2). However any crop including food crops can be grown with reclaimed wastewater after suitable reapplication treatment.

#### Alfalfa:

Although length of growing season at the DVR is of concern, legumes such as alfalfa even if they fix their own nitrogen from the soil, can cycle large amounts of nitrogen from effluent application from depths of up to 6 feet. Over 500 pounds of nitrogen uptake per acre by alfalfa has been reported (1). Therefore it is plausible to consider alfalfa production at a scale that is beneficial to the disposal of treated wastewater, uptake of nitrogen and potential for monetary return. At the present time alfalfa hay is priced quite high at \$20/bale. Average production for a short growing season is approximately 2 Tons/Acre. Each ton averages 20 bales per ton. Monetary return could be potentially \$400/acre for one cutting. Forecast for hay prices in Nevada and California is that hay prices will remain high until these states are not experiencing a drought (LBurnside personal experience). The DVR could support one cutting and then cattle could be grazed on the stubble for the later summer and fall months. Stubble could be irrigated with effluent intermittent with grazing to allow for effluent disposal, drying of soil surface to alleviate potential for compaction, and provide pasture forage.

#### Grass Pasture for Grazing and/Harvest (Hay):

Same price scenario applies to grass hay as it does for alfalfa right now and into the near (2 year) future.

Cool season opportunities are optimal as a mixture of grass species that have growth characteristics that complement each other, such as sod formers and bunch grasses and species that are dormant at different times of the year.

Sod-forming grasses are characterized by their capacity to produce either rhizomes or stolons, each being a modified stem, which extends laterally enabling the grass to develop a firm sod. Rhizomes are underground stems, varying widely in length, often extending 12 inches or more before the tip breaks through the soil crust to form a new shoot. Stolons remain largely at the soil surface with new shoots and roots arising from nodes.

Most grass species classified as bunchgrasses do not produce well developed rhizomes or stolons and therefore have a tufted growth habit as opposed to dense sod. The adventitious buds of

bunchgrasses are found on the basal nodes in crown tissue and produce new tillers which remain within the surrounding leaf sheath of the mother stem.

This feature results in a bunch or tussock type of growth with minimal lateral spreading as occurs with rhizomes and/or stolons. The upward growth means that their growing points are often susceptible to removal by defoliation.

Another advantage of using a mixture of grasses is that, due to natural selection, one or two grasses will often predominate and a mix of species will provide protection against the whole stand being denuded by species specific disease.

#### **Other Crops:**

Marketability and pricing for flax, soybeans and sun flower is sophisticated (a national market rather than a local/regional market such as hay). Thus, marketability of these crops would need to be researched outside the scope of this project if these crops will be under consideration by the District. These crops are currently socially popular. Flax seed is a source of essential fatty acids, soybeans have numerous health wise uses, and sunflower seeds will never go out of fashion.

Table 1. Crops from Table 4-6 (2) seeking the higher potential N, P, K uptake rates (percent of dry harvested material) are as follows:

|                              |                 |                                            | Percent of I | Dry Harveste | d Material |                                                             |

\* Sod farm product – used at golf courses

Wetland Plants - can be sold as plugs or as sod

1 "Crop water requirements" is defined as the total water needed for evapotranspiration, from planting to harvest for a given crop in a specific climate regime, when adequate soil water is maintained by rainfall and/or irrigation so that it does not limit plant growth and crop yield. Source "AQUASTAT Glossary"

**2** These water requirements are estimated based on talking to growers, common types of crops such as the grass species listed above, as well as a web search.

#### 2. What crops can be grazed/and or harvested under effluent irrigation?

All of the species of plants/crops included in table one can be harvested. The following species are not considered as forage for livestock:

Table 2. Plants/Crops not considered as forage for livestock.

|            |              |                                        | Percent o |      | Dry Harvested Material |  |
|------------|--------------|----------------------------------------|-----------|------|------------------------|--|

#### 3. What crops optimize nutrient uptake under effluent irrigation?

Please refer to Table 1. where nutrient uptake is presented as a percentage of dry harvested material.

### Recommendations to be carried forward to the DVR NMP

It is highly recommended that the District consider a mix of crop uses (hay, crop, and wetlands mitigation plant materials). This would allow the DVR a variety of revenue opportunities as well as opportunity to maximize nutrient uptake and effluent disposal.

Another viable option would be to practice hay production for harvest or grazing, or both. One cutting could be harvested due to short growing season from pasture hay fields, followed by grazing on irrigated stubble of that crop.

The Draft DVR Nutrient Management Plan should consider crop/plant alternative opportunities for nutrient uptake for the crops as determined by the District. Nutrient uptake would be considered as a nutrient loss in the nutrient balance of the ranch under the effluent irrigation scenario. This analysis will provide the District with information to be able to determine the crops they want to consider for production and maximize nutrient uptake and effluent disposal.

## **Technical Memo**

| То:    | Hal Bird        |          |                | Date: | March 13, 2009               |
|--------|-----------------|----------|----------------|-------|------------------------------|
| From:  | Leslie Burnside |          | Subject:       |       | Irrigation Methods Tech Memo |
| Projec | t Number:       | 8361.001 | _Project Name: |       | STPUD NMP DVR                |

### **Topic Introduction**

The South Tahoe Public Utility District (STPUD) is seeking guidance regarding the method to provide land application of recycled water to the Diamond Valley Ranch. Guidance provided below is based on published guidance for irrigation of recycled water. The District has expressed that a sprinkler delivery system is a preference. The intent is for Wood Rodgers to provide the pros and cons for each type of delivery system including:

Surface Distribution: flood, furrow, and border. Aerial Distribution: sprinkler, solid set, wheel line and center pivot.

#### **Definitions: (1)**

| (            |                                                                                      |
|--------------|--------------------------------------------------------------------------------------|
| Flood        | uncontrolled application to a vegetated surface via gravity or low head pumping      |
| Furrow       | application to a graded surface field via small ditches between row crops            |
| Border       | application to a leveled field in 20 to 100 foot wide strips, bordered by dikes      |
| Sprinkler    | application of water to the soil through sprinkling or spraying                      |
| Solid Set    | permanently or semi-permanently installed sprinklers are used in blocks of the field |
| Wheel line   | engine movable sprinklers cover the field in sets                                    |
| Center pivot | mechanical sprinkler system with a fixed central water supply moves in a circle to   |
|              | irrigate 20 to more than 400 acres                                                   |
| Linear Move  | Mechanical sprinkler system with end or center feed water supply moves in a straight |
|              | line to irrigate fields up to 5000 feet long                                         |
|              |                                                                                      |

It is understood that the District is planning to have several fields/separate locations that they will irrigate with recycled water. Thus, the District may choose a different irrigation system depending on the crop that will be grown.

Furthermore, the fields that will be irrigated with recycled water will also be available as temporary storage areas on an as needed basis.

### **Information Sought**

- 1. What irrigation delivery systems suit potential crops to be grown?
- 2. What are the advantages and disadvantages for each delivery system that is suited to potential crops to be grown?
- 3. What are the relative costs associated with each irrigation system that is suited to potential crops to be grown?

| Aerial Irrigation - Linear Move                          | High initial capital but less labor                                     |
| Mechanical sprinkler system with end or center feed      | Efficient irrigation with proper design                                 |
| water supply moves in a straight line to irrigate fields | <ul> <li>Not suitable for boggy or sticky soils</li> </ul>              |
| up to 5000 feet long                                     | High instantaneous application rates                                    |
|                                                          | Covers large rectangular fields                                         |

 Table 2. Summary of Irrigation Method Advantages and Disadvantages.

3. What are the relative costs associated with each irrigation system that is suited to potential crops to be grown?

Relative costs associated with types of irrigation methods considered are in bold text in Table 2. Real costs will be dependent on the market and economy at the time of purchase and installation.

## Findings

It is Wood Rodgers opinion that the type of irrigation method chosen should be dependent on the type of crop to be grown, capital budget for initial materials costs, operating budget for pumping if required and labor if needed by the system.

## Recommendations to be carried forward to the DVR NMP

The Diamond Valley Ranch should consider a type of surface irrigation and a type of aerial irrigation to determine hydraulic loading rates.

## **Technical Memo**

| Projec | t Number:       | 8361.001 | _Project Name: | STPUD       | NMP DVR          |

#### **Topic Introduction**

There are areas of the Diamond Valley Ranch (DVR) that may not be irrigable with treated effluent due to evidence of a high groundwater table. To provide a recommendation to the South Tahoe Public Utility District (District) regarding the application of effluent for irrigation at the DVR as part of the development of a Nutrient Management Plan (NMP), soil conditions and depth to groundwater were considered. In August 2008, Wood Rodgers collected soil samples at the DVR. The depth to groundwater and other groundwater indicators were documented in the field, where applicable, in the soil sampling trenches.

#### **Information Sought**

District Fields appropriate for application of treated effluent water for purposes of irrigation are to be identified.

#### Sources Investigated/Used

To determine the area of potentially irrigable lands on the DVR, Wood Rodgers has considered areas that are either currently irrigated with fresh water and/or have been historically irrigated. The proximity of streams, irrigation ditches, springs, and areas of high groundwater as well as infrastructure have also been taken into consideration.

To aid in the August 2008 soil sampling at the DVR, Hal Bird provided Wood Rodgers with a sketch of the layout of the District Fields. Wood Rodgers digitized the outline of the Fields in GIS and attributed them according to their District assigned field numbers. Based upon the topographic information provided by the District associated with the May 15, 2008, aerial photography, the field boundaries were revised. The Field boundaries were adjusted to follow the fence lines, streams, ditches, or roadways. The Field boundaries provide the overall framework for the quantification of potentially effluent irrigable acreage at the DVR.

To prevent contamination of freshwater sources from the application of treated effluent, the following buffers were applied in the determination of irrigable acreage:

• A 25 foot set back from District property lines along Diamond Valley Road. This setback is in excess of other irrigation areas that currently irrigate up to the property line. An overestimation of the buffer allows the District some discretion on irrigation methods.

- A 25 foot set back from the center line of irrigation ditches. In the areas currently under consideration for irrigation by the District, piping or rerouting of fresh water away from the recycled irrigation areas is being proposed, thus no buffers would be required. However, for planning purposes, the District requests a 25 foot buffer from the center of the primary ditches.
- A 25 foot buffer from the edge of Streams should be applied for planning purposes.

The line work in the ditches\_03.shp and streams\_03.shp files, as provided by the District Engineering Department, formed the basis of analysis for the buffer areas. However, some of the line work in these files was adjusted based on the 2008 aerial photography and topographic data to more closely follow the alignments of existing water features.

To provide a 25 foot buffer from the edge of the IC Flood Control Channel and Indian Creek, the top of the streambanks were approximated from the 2008 topographic data. A 25 foot buffer was created in GIS from the developed streambank linework.

The District has requested a 25 foot set back of irrigable lands along District property lines extending along Diamond Valley Road. To determine the location of the set back, a 25 foot offset was applied to the District Field boundaries. The 25 foot set back was not applied to areas designated as high groundwater nor areas defined as "Not a Part of Study". These areas extend to the District Field boundary.

Areas of high groundwater were identified based upon field visits, aerial photography (USA Imagery, April 2007, © 2007 i-cubed. Boundaries and transportation: © 2006 ESRI, AND, TANA), the results of the August 2008 soil sampling, and District groundwater monitoring data.

Please refer to Table 1 and the Soil Sample logs for soil conditions and depth to groundwater for all August 2008 soil sample locations as shown on Figure 1. (Attachment 1).

Ivo Bergsohn provided Wood Rodgers with two spreadsheets containing District well monitoring data and survey data of Alpine County wells as collected by Marrow Surveying. These data were applied to determine the depth to groundwater for the ACMW wells. Well locations with depths to groundwater measuring less than 2.5 feet were classified as areas of high groundwater.

Locations and areas designated as "Not a Part of the Study Area" in Figure 1 either contain infrastructure prohibiting the application of recycled waters, are too small in area to manage, or are limited due to topography.

#### **Findings/Figure References**

District well monitoring data indicate Wells ACMW-01AW south of Field # 4, ACMW-02S adjacent to Field #4 and Field #5, and ACMW-08N and ACMW-08S in Field #9 have registered depths to groundwater less than 2.5 feet as measured from the ground elevation at the well casing. High groundwater levels tend to coincide with the spring months at Wells ACMW-01AW, ACMW-02S, ACMW-08N, and ACMW-08S. However, ACMW-08N and ACMW-08S also register shallow depths to groundwater during fall and winter months.

Groundwater data from Wells ACMW-08N and ACMW-08S are inconsistent with soil characteristics from the August 2008 soil sampling. Soil characteristics from Sampling Site 9a do not indicate the presence of high groundwater, nor was high groundwater present during sampling. However, indicators of high groundwater, such as the presence of gleyed inclusions and characteristics of reduction, were noted at Sampling Site 9b. At this site, groundwater was encountered at an approximate depth of 60 inches.

The alignment of Indian Creek through Field #9 reduces the area of potential application of recycled waters for irrigation purposes. A 25 foot buffer was applied to the top of both stream banks of Indian Creek. Due to the relatively small area located between the stream buffer and the southeast corner of Field #9, this piece was designated as "Not a Part of the Study Area" in Figure 1. The piece is approximately 6 acres in size.

The areas of irrigable acreage and high groundwater have been determined in GIS and are summarized in Table 1. The results correspond to the areas shown in Figure 1. These quantities do not include stream, ditch, or roadway buffers, nor do they include areas designated as "Not a Part of the Study Area".

#### Recommendations to be carried forward to the DVR NMP

Wood Rodgers suggests that additional investigation be undertaken in Fields #5, #6, #7, #9, and #10 to determine the depth to groundwater during the spring, as well as during drier months. This information can be used to confirm whether high groundwater measurements are attributed to flood irrigation or to a seasonally high groundwater table and ultimately which areas of the fields can be used for treated effluent irrigation.

Due to the presence of springs and groundwater seeps at the eastern boundary of Field #1, as well as other locations on the ranch, Wood Rodgers recommends land surveying to better define the wetted area boundaries areas of influence of groundwater features, such as seeps and springs, to better define boundaries for management purposes.

Based upon soil sampling data collected in August 2008 and District groundwater well data, Figure 1 represents irrigable acres that can be used for the application of treated effluent if, as noted for the Fields listed above, additional groundwater elevation monitoring is implemented.

It is further recommended that the District seek concurrence from Lahontan regarding buffer widths for streams and primary irrigation ditches and proposed irrigable acres to allow the District a firm planning foundation for the implementation of a NMP for the DVR.

| Field            | Total Field Area | Area of High | Groundwater           | Irrigat | ole Area              |

\*Please be advised that if mottles in the profile extend from 0 to usually up to 24 inches below ground surface and then disappear, this is an indication of flood irrigation on tight/heavy/clay containing soils/or high application rates – NOT NECESSARY INDICATION OF A SEASONALLY HIGH GROUND WATER TABLE.

\*\* Oxidized Rhizopheres: Indicates wetting and drying conditions as would expect with irrigated conditions. Oxidation occurs on the sides of root channels.

| From:  | Leslie Burnside |          | Subject:       | Grazing Options | s Tech Memo      |
| Projec | t Number:       | 8361.001 | _Project Name: | STPUD           | NMP DVR          |

## **Topic Introduction**

The Diamond Valley Ranch (DVR) has been an operational cattle grazing operation historically, thus it has been assumed that the input of manure to the soil and hydrologic systems has had an impact on the nutrient balance of the ranch. There is one pasture, *District Pasture* which has been somewhat alleviated from consistent cattle grazing for the past ten years. Please refer to Figure 1.

## **Information Sought**

The District Pasture provided an opportunity to:

- **1.** Collect soil samples and compare soil nutrient levels of the District Pasture relative to the rest of the ranch which is consistently grazed on an annual basis
- 2. Determination of whether the input of manure is having an impact on the DVR nutrient balance under existing fresh water irrigation.
- **3.** Determination of whether the input of manure may have an impact on the DVR nutrient balance under treated effluent irrigation application.
- **4.** Provide information necessary to make a determination of whether to maintain the DVR with cattle grazing or discontinue cattle grazing.

## Sources Investigated

Cameron, Di and Moir. Centre for Soil and Environmental Quality, Lincoln University. Nitrogen: Is it a SIDE Issue?

Ohio State University Livestock Management Guide, Bulletin 604-06

## Findings

**1.** Comparison of soil nutrient levels of the District Pasture relative to the rest of the ranch which is consistently grazed on an annual basis:

 Table 1.
 Soil Nutrients - Existing Management - Cattle, Fresh Water Flood Irrigation

| 10                | Not sampled | Not sampled | Not sampled |
| TOTAL             | 75          | 263         | 1513        |
| Avg Grazed Fields | 9           | 31          | 78          |

• These values are summarized from soil samples collected at DVR in August 2008

• \*If there was more than one sample location in any field lab results were averaged

Consistently Grazed – Consistently receiving nutrients via manure

• To convert lb/acre to ppm – use conversion factor based on Bulk Density of soil samples analyzed (conversion factor is as reported form AgSource Harris)

The District Pasture is lower in Nitrogen and Phosphorous, yet higher in Potassium. In-situ soil nutrients within the District Pasture which could be naturally occurring or from past manure inputs may be from several sources and do not appear to be significantly different than that found in the remaining fields of the ranch. Sources of nutrients include manure, fresh irrigation water, atmospheric deposition, etc. In order to mathematically determine the level of significance in the difference of nutrient levels between the District Pasture and the remaining fields, a statistical analysis would need to be conducted which is not within the scope of this Technical Memo.

## 2. Determination of whether in fact the input of manure is having an impact on the DVR nutrient balance under existing fresh water irrigation.

#### Nutrient Budget for DVR using

Ohio State University Livestock Management Guide, Bulletin 604-06

#### Manure and Nutrient Production:

#### Total Manure Output

Assumptions:

- 1000 head that average 1000 lbs/head
- Manure is not stored direct application = handled as a solid
- Each cow produces 11.5 tons of manure per year (see Bulletin column 9)

1000 cows x 11.5 tons per year manure production = 11,500 tons/year

\*Assume livestock on ranch for average of 6 months/year = 5,750 tons of manure/year

Manure Nutrient Production Ν T 4 11 / T

| N 5750 T/Yr x 7.4 lb/Ton                             | = | 42,550 lb/Yr |
|------------------------------------------------------|---|--------------|
| P <sub>2</sub> O <sub>5</sub> 5750 T/Yr x 6.0 lb/Ton | = | 34,500 lb/Yr |
| K <sub>2</sub> O 5750 T/Yr x 8.3 lb/Ton              | = | 47,725 lb/Yr |

Acres of each Crop and Average Yield per Acre

Pasture Grass Maintenance Current Crop

Production = 2 to 4 Tons/Acre (please see attached Common Agronomic & Horticultural Crop Codes) Total Acres (this is the sum of field acres minus high GW areas) 903 acres<sup>1</sup> <sup>1</sup> Based on 2/4/09 Irrigable Acres Tech Memo findings

#### Table 2. **Recommended Nutrient Needs**

Livestock Management Guide, Bulletin 604-06. The lbs/per acre used as Nutrient Needs in this table are those taken form the Ohio State University (attached)

| Сгор                         | Yield <sup>1</sup> | Irrigable<br>Acres | Nutrient Needs = Yield x Acres x Crop Removal<br>(See Bulletin Tables 5 and 6) |                                                                         |                                               |  |

Calculations for Table 3.

<sup>1</sup> N Nutrient Needs = 40 lb/ton x 2 tons/acre/year x 255 acres 40 lb/ton x 3 tons/acre/year x 67 acres 40 lb/ton x 4 tons/acre/year x 580 acres

 $^{2}$  P<sub>2</sub>O<sub>5</sub> Nutrient Needs = 13 lb/ton x 2 tons/acre/year x 255 acres 13 lb/ton x 3 tons/acre/year x 67 acres 13 lb/ton x 4 tons/acre/year x 580 acres

<sup>3</sup> K<sub>2</sub>O Nutrient Needs = 50 lb/ton x 2 tons/acre/year x 255 acres 50 lb/ton x 3 tons/acre/year x 67 acres 50 lb/ton x 4 tons/acre/year x 580 acres

#### Table 4. Comparison of Manure Nutrient Inputs and Nutrient Crop Needs

|                                                                             | N<br>(max 175 lbs/ac) | P <sub>2</sub> O <sub>5</sub> | K <sub>2</sub> O |
|-----------------------------------------------------------------------------|-----------------------|-------------------------------|------------------|
| Nutrient Available from Manure                                              | 42,550 lb/Yr          | 34,500 lb/Yr                  | 47,725 lb/Yr     |
| <b>Crop Nutrient Needs/Removal</b><br>See Table 3 above                     | - 121,240 lbs/yr      | - 39,403 lbs/yr               | - 151,550 lbs/yr |
| Whole Ranch Nutrient Balance (What is available from + Manure – Crop Needs) | - 78,690 lb/Yr        | - 4,903 lb/Yr                 | - 103,825 lb/Yr  |

Based on the comparison provided in Table 4., under a fresh water irrigation regime the DVR is in a deficit for major nutrients, Nitrogen, Phosphorous and Potassium.

**3.** Determination of whether the input of manure may have an impact on the DVR nutrient balance under treated effluent irrigation application.

The only method by which to be absolutely sure what the nutrient balance impacts are, would be to irrigate with the Districts treated effluent with a know quantity of nutrients as an input, sample soils annually to determine assimilation of nutrients in the soils for grazed and ungrazed pastures. However, we have been asked to forecast what this management option might result in for this tech memo.

The scenario of treated effluent irrigation application with flood irrigation method and pasture grass and irrigating 15 days per month for eight months of the year gives us an idea of what the relative impacts may be.

#### Table 5. Comparison of Manure Nutrient Inputs and Treated Effluent Nutrient Inputs and Nutrient Crop Needs

Table 5 is the same as Table 4, however it includes the addition of nutrient Nitrogen as an input as added by the STPUD treated effluent.

|                                                                                | N<br>(max 175 lbs/ac) | P <sub>2</sub> O <sub>5</sub> | K <sub>2</sub> O |
|--------------------------------------------------------------------------------|-----------------------|-------------------------------|------------------|
| Nutrient Available from Manure                                                 | 42,550 lb/Yr          | 34,500 lb/Yr                  | 47,725 lb/Yr     |
| Nutrient Available from Treated Effluent                                       | 79,320 lb/yr 1        |                               |                  |
| <b>Crop Nutrient Needs/Removal</b><br>See Table 3 Above                        | - 121,240 lbs/yr      | - 39,403 lbs/yr               | - 151,550 lbs/yr |
| Whole Ranch Nutrient Balance (What is available<br>from + Manure – Crop Needs) | 630 lb/Yr             | - 4,903 lb/Yr                 | - 103,825 lb/Yr  |

 $^{1}4.5$  MGD x 17.6 mg N/1 x 3.79 l/gal x 1 lb/454g x 1 g/1000mg = 661 lb N/day; 4.5 MGD avg daily discharge, from STPUD; 17.6 mg/l avg total N in HPR water, from STPUD; Remainder of terms are conversion factors. 661 lb N/day x 15d/mo x 8mo/yr = 79,320 lb N/yr

Based on the comparison provided in Table 5., under a treated effluent water irrigation regime the DVR is in a deficit for major nutrients Phosphorous and Potassium, and has a small excess of Nitrogen.

# Table 6. Comparison of Treated Effluent Nutrient Inputs and Nutrient Crop Needs with out Livestock Grazing.

Table 6 is the same as Table 5, however the input of nutrients from manure have been removed (no grazing and irrigation with treated effluent.

|                                                                             | N<br>(max 175 lbs/ac)     | P <sub>2</sub> O <sub>5</sub> | K <sub>2</sub> O |

| Whole Ranch Nutrient Balance (What is available from + Manure – Crop Needs) | - 41,920 lb/Yr            | - 39,403 lbs/yr               | - 151,550 lbs/yr |

 $^{1}$  4.5 MGD x 17.6 mg N/1 x 3.79 l/gal x 1 lb/454g x 1 g/1000mg = 661 lb N/day; 4.5 MGD avg daily discharge, from STPUD; 17.6 mg/l avg total N in HPR water, from STPUD; Remainder of terms are conversion factors. 661 lb N/day x 15d/mo x 8mo/yr = 79,320 lb N/yr

Based on the comparison provided in Table 6., under a treated effluent water irrigation regime the DVR is in a deficit for major nutrients Nitrogen , Phosphorous and Potassium.

Summary:

Under a treated effluent irrigation regime, irrigating 15 days per month for 8 months, grass hay pasture, with livestock grazing the DVR (1000 head for 6 months) results in an estimated excess of available major nutrients Nitrogen, and has a deficit for Phosphorous and Potassium (Table 5).

|                                                                             | Ν                | $P_2O_5$      | K <sub>2</sub> O |
|-----------------------------------------------------------------------------|------------------|---------------|------------------|
|                                                                             | (max 175 lbs/ac) |               |                  |
| Whole Ranch Nutrient Balance (What is available from + Manure – Crop Needs) | 630 lb/Yr        | - 4,903 lb/Yr | - 103,825 lb/Yr  |

Under a treated effluent irrigation regime, irrigating 15 days per month for 8 months, grass hay pasture, with no livestock grazing the DVR results in an estimated deficit of all major nutrients Nitrogen, Phosphorous and Potassium (Table 6).

|                                                                             | N<br>(max 175 lbs/ac) | P <sub>2</sub> O <sub>5</sub> | K <sub>2</sub> O |
|-----------------------------------------------------------------------------|-----------------------|-------------------------------|------------------|
| Whole Ranch Nutrient Balance (What is available from + Manure – Crop Needs) | - 41,920 lb/Yr        | - 39,403 lbs/yr               | - 151,550 lbs/yr |

These calculations have not been subjected to statistical accuracy, nor has the Nitrogen input from manure been verified.

Proposed Irrigable acres have been reviewed by the District in the Recommended Fields Technical Memo, February 4, 2009

## Recommendations to be carried forward to the DVR NMP

The objective for this Tech Memo was to use available information and determine if livestock grazing nutrient inputs from manure would have an impact on the nutrient balance for the DVR under a treated effluent irrigation regime. This information will be useful to the District in their decision making process on whether to continue livestock grazing under a treated effluent irrigation regime.

#### Grazing and treated effluent irrigation:

Nutrient input from manure will result in excess of available major nutrients Nitrogen and a deficit for Phosphorous and Potassium (Table 5).

Livestock grazing removes nutrients from the ranch through harvesting of the crop while also providing nutrient input (manure) to a system. Managed grazing of pasture hay also assists in maintaining the quality of the crop. If pasture grass is not grazed, it will become "wolfey" or decadent where the centers of the plants will begin to die out as the plants stagnate due to shading from growth not removed. This is very similar to what the layman observes when a landscaped lawn is not mowed.

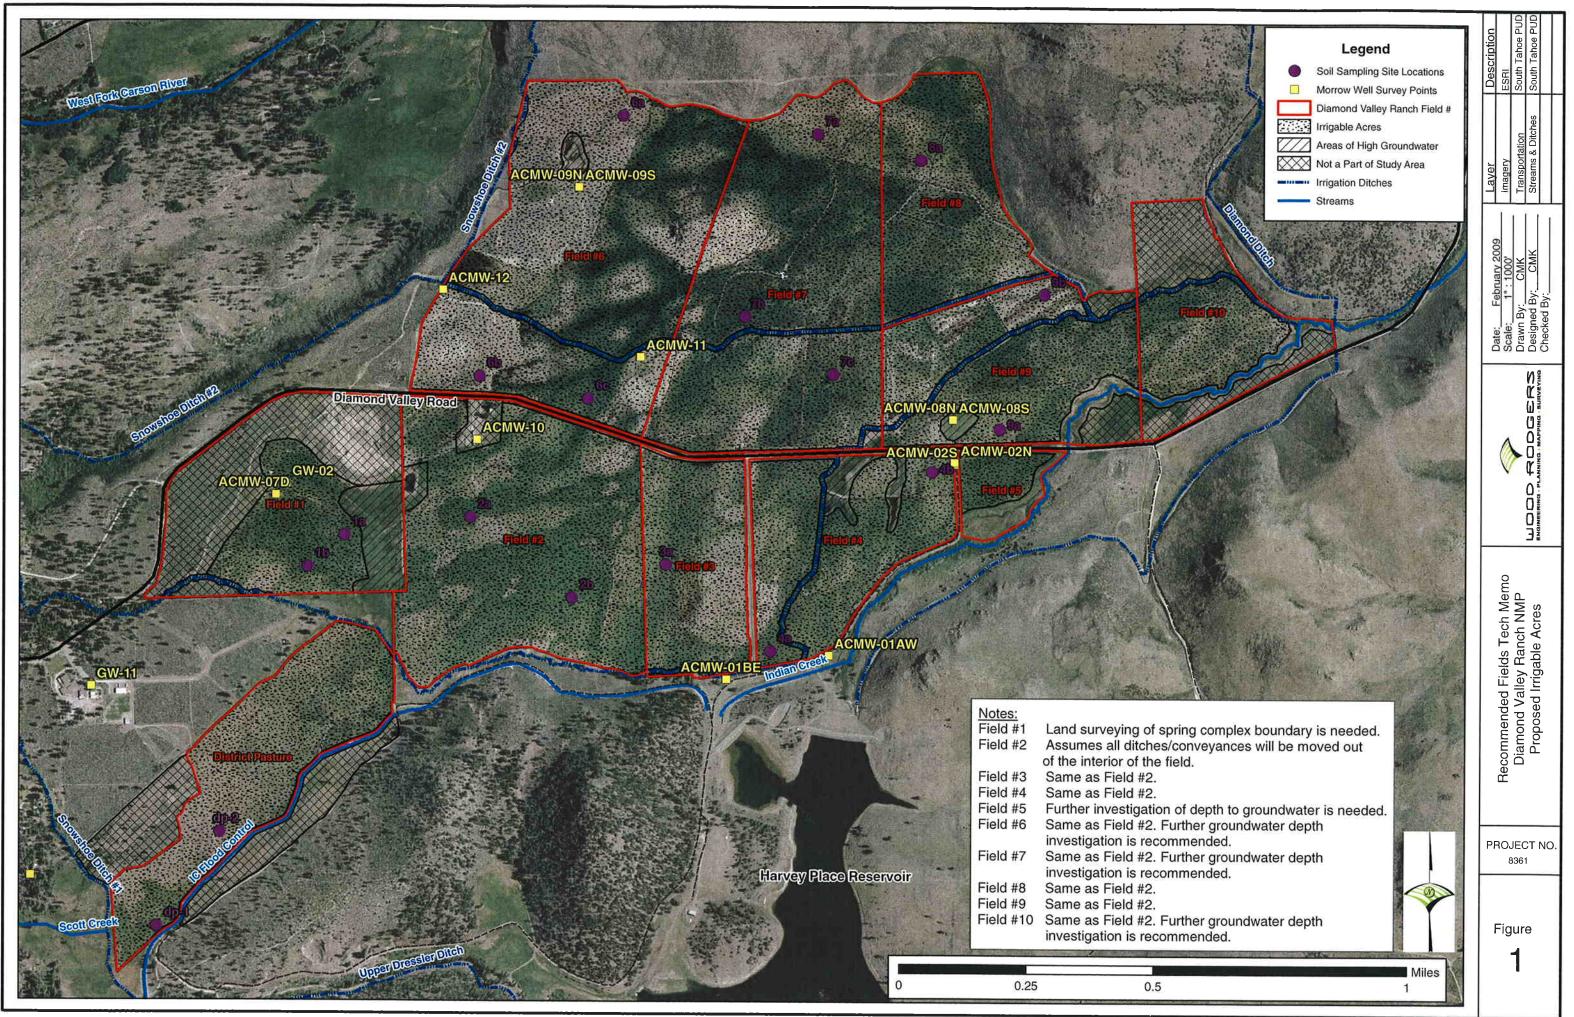

<u>Removal of grazing under treated effluent regime:</u> Under a treated effluent irrigation regime, irrigating 15 days per month for 8 months, grass hay pasture, with no livestock grazing the DVR results in an estimated deficit of all major nutrients Nitrogen, Phosphorous and Potassium (Table 6).

It is recommended that manure be analyzed at a statically accurate level to provide precise nutrient inputs before a decision is made regarding livestock grazing of pasture or any other crop that also provides grazing opportunities. In addition, calculations need to be verified by the District regarding times frames and type or irrigation chosen.

| Field            | Total Field Area | Area of High Groundwater |                       | Irriga | able Area             | Production |

## APPENDIX 2 SUPPLEMENTAL INFORMATION

## 

#### http://www.ndep.gov

#### WTS-1B: GENERAL CRITERIA FOR PREPARING AN EFFLUENT MANAGEMENT PLAN

#### **GENERAL NOTES:**

The Nevada Division of Environmental Protection (NDEP) must be contacted whenever the use of reclaimed water is planned in order to determine the appropriate regulatory oversight requirements. NDEP shall also be available to assist the applicant in preparing the effluent management plan (EMP).

The Nevada Division of Water Resources (775) 687-4380 must be notified of the plan to use reclaimed water in order to address requirements for secondary water rights. Also, the Nevada State Health Division (775) 687-9521 should be consulted to ensure the use of reclaimed water is consistent all water supply protection requirements. Finally, please be aware that the local government and water purveyor may have rules on reclaimed water usage and should be consulted.

#### **GUIDANCE INTRODUCTION:**

Pursuant to NAC 445A.275.1(b), NDEP must issue a discharge permit for the use of reclaimed water. As part of this permitting process, NAC 445A.275.1(a) states that an EMP must be submitted and approved prior to the use of reclaimed water. This guidance was prepared to assist the permittee in preparing a satisfactory EMP. Please be aware that the extent of information and content for each individual EMP will vary for the different types of reclaimed water use, so not all portions of this guidance may apply to your particular EMP.

This guidance was organized to cover only existing usages of reclaimed water in Nevada. Items that the Division deems a requirement are so marked in the document and items that are simply recommendations are so marked. Information on any guidance referenced in WTS-1B may be gathered by contacting this Bureau.

Past guidance documents for reclaimed water use (WTS-1, WTS-9, and the outline format), are now effectively replaced by this guidance and WTS 1A (General Design Criteria for Reclaimed Water Irrigation Use). This Guidance is considered a dynamic document, and revisions may be made in the future as changes in reclaimed water usage regulations dictate.

Thanks is given to the Reuse Nevada Committee for their assistance in helping NDEP prepare this guidance.

The EMP is intended for use by the reuser (golf course superintendent, farmer, park maintenance worker, industrial worker, etc.) so it should be written in a user friendly format. The use of illustrative figures, maps, and tables throughout the EMP is highly recommended. The EMP should be bound in a loose leaf binder to facilitate updates. The date of printing for the EMP and all subsequent revisions must be shown on the title page of the EMP.

This document does not replace best professional judgement in reuse system management and NDEP reserves the right to require further information and review additional factors as needed.

| NOTIFICATION SIGN EXAMPLES                     | Appendix Four  |
| REUSE REFERENCE LIST                           | Appendix Five  |
| NEVADA ADMINISTRATIVE CODE - REUSE REGULATIONS | Appendix Six   |

## **KEYWORDS**

#### AIR GAP:

Generally, the safest method of back flow prevention control. For this document, it is defined to be an unobstructed vertical distance through the free atmosphere between the lowest opening from any pipe conveying potable water to the flood level

rim of any container with treated effluent. The Uniform Plumbing Code details the requirements for Air Gaps and enforcement is the role of the local water purveyor and/or health authority.

#### **BUFFER ZONE:**

NAC 445A.076 defines a buffer zone to be the shortest distance between the boundary of the site being irrigated with reclaimed water and either; **one**, the property line boundary of the site; **two**, a posted public warning sign, or; **three**, any point where the property is open to public access, whichever is least. NAC 445a.276 lists the various buffer zones for spray irrigation sites based on reclaimer water quality and type of site being irrigated.

**DMR:** Discharge Monitoring Report. A table-formatted report where results from permit sampling and monitoring are recorded for submittal to NDEP.

#### **COLIFORM:**

Bacteria from feces of mammals which is used as an indicator of pathogenic organisms.

#### **RECLAIMED WATER:**

Domestic Wastewater that has been treated to secondary treatment standards and disinfected to levels necessary (per NAC 445A.276) for the chosen method of reuse. Other terms for this water include Treated Effluent, Reuse Water, and Recycled Water.

**SAR :** Sodium adsorption Ratio, a ratio determined from the concentration (milliequivalents/liter) of sodium, calcium, and magnesium in water. It is used as an indicator of potential soil problems.

$$\mathbf{SAR} = \frac{\mathbf{Na}}{\left[(\mathbf{Ca} + \mathbf{Mg})/2\right]^{1/2}}$$

A modification of this ratio, termed the adjusted SAR, considers the changes in calcium solubility in soil water. The procedure for determining this ratio is listed in <u>Wastewater</u> Engineering Treatment, Disposal and Reuse. 1991.

#### **SOIL LEACHING:**

Irrigation practice of applying water to soils in an effort to drive salts beyond the crop root zone. The rate is a function of crop salinity tolerance and salt level in irrigation water.

#### **SPRAY IRRIGATION:**

For purposes of this guidance, spray irrigation is categorized into three types; solid set (golf courses), move-stop (wheel lines), and constant move (center pivot) systems.

#### **SURFACE IRRIGATION:**

Surface irrigation is categorized as either flood irrigation or drip irrigation. Flood irrigation is further subdivided into ridge/furrow systems and graded borders.

## **GENERAL ITEMS FOR ALL EMP'S**

#### **REQUIREMENTS:**

#### A. <u>Overview of Project</u>

A comprehensive overview of the reclaimed water application for the project. Outline the distribution system, application site, application method, and permit responsibilities. Use figures to illustrate the general system layout.

#### B. <u>Staff Listing</u>

A listing of supervisors and key responsible staff at the reuse site, including a description of their accompanying responsibilities. This list shall include each person's phone number, cell phone number, mailing address, and e-mail address (if available).

#### C. Discharge Permit

A complete copy of the active ground water discharge permit issued by this Division shall be inserted into the EMP.

#### D. <u>Reuse Provider - User Agreement (If Applicable)</u>

A copy (if applicable) of the reuse agreement between the reclaimed water supplier and the user/permit holder. This agreement should include an updatable copy of the reclaimed water quality analysis and special restrictions that may be in place on the reuse.

#### E. <u>Communication Procedure</u>

The communication procedure(s) between all parties involved in the transfer of reclaimed water, storage of reclaimed water, and use of reclaimed water shall be outlined in the EMP.

#### F. <u>Hygiene</u>

A brief document describing the proper hygiene of working with reclaimed water. This document should be written in English and any other languages deemed appropriate for the site. (Sample documents are provided in Appendix 4)

#### G. <u>Reclaimed Water Run-Off Control Plan</u>

- 1. Identification of areas where a release off the site may occur and how it will be detected (daily rounds, pressure readouts, etc.).
- 2. Steps that will be taken to control the release.
- 3. Phone numbers for key personnel involved in the release response plan and persons who are responsible for reporting the release to NDEP.

#### G. <u>Reclaimed Water Run-Off Control Plan (continued)</u>

- 4. Description of the permit requirements for reporting a release to NDEP. This includes notification by phone, at (775) 687-4670 as soon as the release is identified and controlled (within 24 hours). Also, a written report on the release (discharge) and the methods used to mitigate the release must be submitted to the NDEP within five days. This report shall list:
  - i. the time and date of the discharge;
  - ii. exact location and estimated amount of discharge;
  - iii. flow path and bodies of water which the discharge reached;
  - iv. the specific cause of the discharge; and
  - v. the preventive and/or corrective actions taken.

#### H. <u>Cross Connection and Back Flow Prevention (If applicable)</u>

Summarize the cross connection control plan and back flow prevention plan that has been accepted by the Health Authority and/or water purveyor. Reference all figures that show these controls.

I. <u>Discharge Monitoring Reports (DMR'S)</u>

Outline of the procedure for completing the permit required DMR from field readings and laboratory data sheets. This section shall include a sample DMR to guide the reuser.

## **RECLAIMED WATER IRRIGATION - GENERAL ITEMS**

A. Irrigation Plan

Provide a summary of the irrigation plan for the site(s). This summary shall detail the times of irrigation, the application rates, and flow measuring procedures. Critical focus shall be given to preventing run-off of reclaimed water from the site(s) and reducing reclaimed water ponding. For sites using automated or computer controlled irrigation systems, please include a brief description of how the system operates.

Depending upon the site type and physical location, several items that should be addressed in the irrigation plan are:

- 1. A plan to avoid irrigation during or just after significant precipitation events.
- 2. A plan to provide sufficient drying time for soils (after irrigation) before allowing animal grazing. It's recommended that the grazing periods be limited, to the best extent possible, to reduce soil compaction.
- 3. Plans to harvest crop(s) annually (if applicable).
- 4. A plan to prevent irrigation on frozen soils or saturated soils.

#### B. <u>Site Maps</u>

A detailed site map for the irrigation site(s). This map shall delineate the surrounding water courses, storm water controls, buffer zones (if applicable), prevailing wind direction, surrounding dwelling units, and any wells within 250 feet of the reuse site boundary.

#### C. Irrigation System

Schematic or scaled map of the reuse site that shows the conveyance system and components for the reclaimed water. This includes details on the location of control valves, drain valves, air gaps, flow meters, pumps, and other key components that the reuser will operate and maintain.

#### D. Ponds

Operation and maintenance plan for the reclaimed water storage ponds (if applicable). Items to address could include water level recording devices and storage volume estimates, algae control, odor control, reclaimed water transfer procedures, free board requirements, berm inspection, weed control, vector control, flow recirculation, notification signage, and mechanical aeration (Note: the generation of aerosols from aeration equipment should be minimized to limit drift).

#### E. <u>Treatment Systems (if applicable)</u>

The operation and maintenance plans for treatment units that may be required to meet permit limits are to be included in the EMP. This may include such units as sand filters, disinfection systems, or any chemical treatment systems.

#### F. <u>Crop/Turf Management Plan</u>

It is recommended that management plans addressing maintenance of a healthy crop be summarized in the manual. Items relevant to this pursuit include soil leaching practices, soil amendment applications, soil chemistry monitoring, and other specific procedures for the site's crop. Please contact the local agricultural agency for guidance.

#### G. Storm Water

Storm water control structure maintenance. This shall include a maintenance program for diversion berms, conveyance ditches, conduits, and pump systems (if applicable).

#### H. <u>Sampling</u>

Sampling plans required by the permit must be outlined in the EMP. The proper QA/QC for sample preservation, sample holding times, sample containers, and chain of custody

This includes the procedures for collecting a ground water sample from a monitoring well and (if applicable) collecting a reclaimed water samples. Groundwater sampling protocol guidance is available from the Division.

#### I. <u>Water Balance</u>

Completion of a water balance is required by reuse permits. The procedures for completing the water balance summary for the site(s) must be clearly outlined in the EMP. Completed worksheet "1-B" from Appendix One, or a comparable form, should be included to present the design assumptions and to provide guidance for filling out subsequent reporting forms. Blank worksheets should also be included. Sample forms are attached in Appendix One. Information from these worksheets can be used by the permittee in completing the Annual Report that is typically required to be submitted with the fourth quarter DMR.

#### J. <u>Nitrogen Balance</u>

Completion of a nitrogen balance is required by reuse permits if the total nitrogen in the effluent is greater than 10 mg/l total nitrogen. The procedures for computing the total amount of nitrogen applied to the site(s) must be clearly outlined in the EMP. This shall include the mass of nitrogen applied from the reclaimed water and fertilizers. Completed Worksheet "2-B" from Appendix Two, or a comparable form, should be included to present the design assumptions and to provide guidance for filling out subsequent reporting forms (Worksheet "2-C" and DMR forms). Blank worksheets should also be included. Sample forms are attached in Appendix Two. Information from these worksheets can be used by the permittee in completing the Annual Report which is typically required to be submitted with the fourth quarter DMR.

#### K. Signage

Any site using reclaimed water for irrigation or other uses shall post a notice warning the general public to avoid contact with the reclaimed water (NAC 445A.2752). Signage examples are included in Appendix Five for reference. Score cards at golf courses are one option for providing notification to the public that reclaimed water is being used for irrigation.

## **ADDITIONAL RECLAIMED WATER IRRIGATION ITEMS FOR:**

## SPRAY IRRIGATION

#### A.Run-Off Containment Berms

Maintenance plan for containment berms that serve to prevent the surface flow of reclaimed water off the site boundary (NAC 445A.2754) if there is a significant line break or other failure. These berms are site specific requirements and therefore may not apply to your site.

#### B. Freezing Weather Protection

Depending upon the site location, necessary maintenance items to prevent freezing and damage to the distribution system should be included. Items to address are piping insulation, drains, or valve enclosures.

#### C. Drinking Water Fountain Protection and Food Serving Areas

Plans to cover or protect drinking water fountains or water stations located on the reuse site prior to the start of irrigation shall be included. Additionally, plans to shield areas where food is handled should be presented.

#### D.Buffer Zone Controls

Describe the required buffer zones for the quality of reclaimed water used (see table on next page). Also, list procedures for maintaining spray irrigation within these zones. The irrigation plan should control the drifting of aerosols beyond the buffer zones (NAC 445A.2754).

#### E. Irrigation Scheduling

Spray irrigation under Category B, C, and D criteria (see regulations) should be conducted during the nighttime hours at public areas (parks, golf courses, etc.) and the public shall be restricted from entering the site during the irrigation period.

Treated effluent irrigation for golf courses shall primarily take place during times after the course is closed and shall cease one hour before the course opens for play in the morning. The irrigation system can be operated briefly during daylight hours when golfers are not present or approaching provided the operator ensures that the public are not exposed to effluent spray or wet grass. Daytime irrigation system operation or hand watering shall be supervised at the site of irrigation by course personnel at all times.

Specific areas within the site that are first accessed (example: first few holes on golf course) by the public should be irrigated during the initial stages of the watering cycle to allow drying time before the public is permitted to enter.

#### F. Agricultural Irrigation

All irrigation shall ensure that the public is not exposed to effluent spray. Appropriate buffers shall be maintained according to Category of effluent used. All sites shall be fenced and posted.

#### G. Spray Irrigation with Reclaimed Water: Category B, C, D, and E

- 1. Plans to control public *access* to the irrigation site during times of reclaimed water application are required. Relevant items include fencing, adherence to the required buffer zones (if applicable), and notification of reclaimed water usage. The quality of reclaimed water will dictate the level of access controls (see Table next page).
- 2. Plans to control public *contact* with reclaimed water at the site are required. Relevant items include prevention of ponded water, notification signage, irrigation scheduling (ex. night time irrigation), and notification of reclaimed water usage on scorecards, signage or other related documents available to the public. Quality of reclaimed water will dictate level of contact controls required (see Table next page).

| Category B                                                                                                                     | Category C                                                                                                                     | Category D                                                                                                                      | Category E                                                                                                 |
|--------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------|
| Public Access is<br>Controlled. Human<br>contact with reclaimed<br>water cannot reasonably<br>be expected to occur.            | Public Access is<br>Controlled. Human<br>contact with reclaimed<br>water does not occur.                                       | Public Access is<br>prohibited during<br>irrigation periods. No<br>human contact due to<br>site isolation.                      | Public Access is<br>prohibited during<br>irrigation periods. No<br>human contact due to<br>site isolation. |
| Areas covered in all<br>categories, plus parks,<br>playgrounds,<br>commercial lawns, and<br>residential lawns.                 | Golf courses, green belts, cemetery, and other areas                                                                           | Pasture Lands, other agricultural uses                                                                                          | Pasture Lands, other agricultural uses                                                                     |
| No Buffer Zone                                                                                                                 | 100 ft. Buffer Zone                                                                                                            | 400 ft. Buffer Zone                                                                                                             | 800 ft. Buffer Zone                                                                                        |

## ADDITIONAL RECLAIMED WATER IRRIGATION ITEMS FOR:

## **SURFACE IRRIGATION**

#### A.FLOOD IRRIGATION:

#### 1. Irrigation Methodology

Operational plan(s) for flow distribution. Relevant items to address include promoting even spreading of reclaimed water over the site(s), reducing soil erosion at the distribution points, and operation of the tailwater recovery system operation (if applicable).

2. Containment Berms and Detention Areas

A maintenance plan and inspection schedule for containment berms and detention areas (NAC 445A.2754) that are in place to prevent the run-off of the reclaimed water from the site(s) is required.

#### **B. DRIP IRRIGATION**

1. Irrigation Methodology

Operational plan for flow distribution. Relevant items include site inspections (checking for line breaks, etc.) and emitter line maintenance (clogging controls).

C.SUBSURFACE IRRIGATION

The operation of the subsurface irrigation system shall be such that no surfacing or ponding of treated effluent occurs. All piping and control valves shall be properly identified as reclaimed

water appurtenances (purple coloring, reclaimed water wording, etc.).

Specific tasks for freezing protection shall be conducted as needed.

## **CONSTRUCTION USAGE**

#### A.DUST CONTROL

#### 1. Fecal Coliform Levels

The typical minimum fecal coliform limits for this application are 200mpn (cfu)/100 ml for the 30 day geometric mean and 400 mpn (cfu)/100 ml for a daily maximum.

#### 2. <u>Application Items</u>

Plans for controlling the application rate shall address the prevention of ponded reclaimed water. Also, a plan to control the generation of aerosols and the migration of aerosols from the site(s) should be developed. Methods to prevent the application of reclaimed water near water courses (rivers, streams, and lakes) must be presented.

#### 3. Reclaimed Water Dust Control Trucks

Tank trucks and other equipment that hold reclaimed water shall be properly identified with notification signs. Tank trucks that carry reclaimed water shall not be used to carry **potable water**. It is recommended that the tanks be cleaned and disinfected after the project

is complete. Please consult the State or local health authority on rules that may be in place for this criteria

### **INDUSTRIAL USAGE**

#### A.COOLING WATER

1. Fecal Coliform Level

The typical minimum fecal coliform limits for this application are 2.2 mpn (cfu)/ 100 ml for a 30 day geometric mean and 23 mpn (cfu)/100 ml for a daily maximum.

2. Application Items

List operational controls to reduce aerosol drift.

NDEP recommends that facilities institute operational methods for treatment (lime addition, alum, etc.) to handle scaling, corrosion, fouling, and biological growth throughout the system. This will help reduce line clogging and other system problems. Also, if algae growth is a concern, chlorine can be used to control algae growth provided the water is not discharged to a water course. This should also help reduce the formation of Legionella.

## **OTHER USES OF RECLAIMED WATER**

A. Site specific management plans for the use of reclaimed water will be considered on a case by case basis with appropriate controls and requirements determined by the NDEP.

### WTS-1B: APPENDIX ONE

### PLANT CONSUMPTIVE USE WORKSHEET

The consumptive use equation for determining the crop's water requirement takes into account precipitation, evapotranspiration, the efficiency of the irrigation system, and the salt tolerance of the plant species. The salt tolerance of the plant species is used to calculate the leaching requirement (Lr) to remove excess salts from the root zone. Excess salts within the soil cause the plant cells to expend more energy adjusting the salt concentration within the plant tissues, and therefore, less energy is available for vigorous plant growth. The hydraulic loading rate and the TDS to ECw conversion equation included below are derived from <u>Wastewater Engineering: Treatment, Disposal, and Reuse</u>, (Metcalf and Eddy, 1991), the equation for the leaching requirement is from the <u>Nevada Irrigation Guide</u>, (USDA, Soil Conservation Service, 1981).

$$Lw_{(c)} = \underline{(ET-P)}$$

$$Lr = \underline{ECw}$$

$$[(5 \text{ x ECe})-ECw]$$

where:

 $Lw_{(c)}$  = Allowable Hydraulic Loading Rate Based on Crop Water Needs (in/yr);

- ET = Evapotranspiration Rate (in/yr);
- P = Precipitation Rate (in/yr);
- Lr = Leaching Requirement (%, expressed as a fraction);
- E = Efficiency of Irrigation System (%, expressed as a fraction)
  - For example: 75% = 75/100 = 0.75; example efficiencies are included below;
- ECe = Salinity Tolerance of Plant Crop  $(mmho/cm \text{ or } dS/m)^{(1)}$ ;
- ECw = Salinity of Applied Effluent (mmho/cm); If TDS is supplied by the laboratory, see conversion below; and
- TDS = Average Total Dissolved Solids in Applied Effluent (mg/l).

#### "ET" - Evapotranspiration

Evapotranspiration is defined as the "loss of water from the soil both by evaporation and by transpiration from the plants growing thereon" (Websters Dictionary, 1990). Since different plants transpire at different rates, a crop coefficient (Kc) can be used to modify the potential ET for a particular area. Values for Kc vary depending upon the geographical location of the crop, and the species grown. If a crop coefficient can be determined, when multiplied by the potential ET rate, the result is a more accurate estimate of ET for an irrigation site. The Division recommends that reusers contact local agriculture representatives identified in Appendix Five for further crop-specific and regional information.

WTS-1B: Appendix One Page 2

#### "E" - Irrigation Efficiency

The irrigation system efficiency is related to how effective the method is in delivering the irrigation water equally to all parts of the crop. Example values for efficiency  $are^{(4)}$ :

| Sprinkler<br>Irrigation Type         | Application Efficiency | Surface<br>Irrigation Type            | Application Efficiency |
|--------------------------------------|------------------------|---------------------------------------|------------------------|
| Solid Set                            |                        | Narrow Graded<br>Border (< 15' wide)  | 0.65 - 0.85            |
| Portable Hand Move                   |                        | Wide Graded<br>Border (<100' wide)    | 0.65 - 0.85            |
| Wheel Roll                           | 0.70 - 0.80            | Level Border                          | 0.75 - 0.90            |
| Center Pivot or<br>Traveling Lateral |                        | Straight or Graded<br>Contour Furrows | 0.70 - 0.85            |
| Traveling Gun                        |                        | Drip                                  | 0.70 - 0.85            |

#### "ECe" - Salinity Tolerance of Plant Crop

The plant salt tolerance is crop-specific, and can be obtained from the local Extension Service, literature, or other reputable sources. The low end of the range identifies the ECe value which would result in a 0% reduction of crop yield. The upper end of the range identifies the ECe value which could result in a 25% reduction of crop yield<sup>(4)</sup>.

Example ECe's:

Annual Ryegrass<sup>(2)</sup> = 3 to 6 mmho/cm or dS/m Perennial Ryegrass<sup>(2,4)</sup> = 5.6 to 8.9 mmho/cm or dS/m Bermudagrass<sup>(2,4)</sup> = 6.9 to 10.8 mmho/cm or dS/m Tall Fescue<sup>(2,4)</sup> = 3.9 to 8.6 mmho/cm or dS/m Alfalfa<sup>(3,4)</sup> = 2.0 to 5.4 mmho/cm or dS/m

#### "ECw" - Salinity of Applied Effluent

Direct measurement of ECw is typically preferred. However, if the laboratory has supplied the reuser with a concentration of TDS, an approximate conversion<sup>(4)</sup> is ECw  $\approx$  TDS  $\div$  640. This conversion is considered accurate within 10%. The value for ECw or TDS is obtained from the treatment plant supplying the effluent. For site design, an average value can be used. For completion of the required annual balance report, the actual analytical results from Discharge Monitoring Reports should be used.

<sup>(1)</sup> For clairty in this document, the unit for electrical conductivity (EC) is expressed as mmho/cm. However, EC can also be expressed in decisiemens per meter, dS/m.

1 mmho/cm = 1 dS/m

| (H)                 | Leaching Requirement (Lr, %, expressed as a fraction) = (D) $\div$ (G) =                                                                                                                                                   |
| (I)                 | 1 - (H) =                                                                                                                                                                                                                  |
| (J)                 | Efficiency of Irrigation System (E, %, expressed as a fraction) =                                                                                                                                                          |
| (K)                 | (J) x (I) =                                                                                                                                                                                                                |
| (L)                 | (C) $\div$ (K) = Lw <sub>(c)</sub> = (inches/year)                                                                                                                                                                         |

If the water use rate calculated in ("L") above is the lowest application volume calculated between the annual Consumptive Use Limit (This Worksheet) and the Nitrogen Limit (Worksheet 2-A), then fill out Worksheet 1-B to estimate the planned maximum daily flow for the site.

## Worksheet 1-B

#### **CONSUMPTIVE USE REQUIREMENT WORKSHEET:** Maximum Loading Rate Based on Plant Water Use Requirements

| Page          | of (                   | Crop | Type = |                        |   | -                     |
|---------------|------------------------|------|--------|------------------------|---|-----------------------|
| $Lw_{(c)} = $ | (ET-P)<br>[E x (1-Lr)] | _;   | Lr = _ | ECw<br>[(5 x ECe)-ECw] | ; | ECw $\approx$ TDS÷640 |

Monthly values for evapotranspiration are dependent on the crop type and regional area of the site, as well as the crop coefficient if known. Monthly precipitation is also regional. The values for ET and P can be obtained from the local extension service, literature, or other reputable source. Please see the explanation in the "WTS-1B: Appendix One" text for futher discussion of crop coefficients.

To calculate the monthly value for  $Lw_{(c)}$ , perform the calculation for each month as outlined in Worksheet 1-A, and input the result in the table below. Since this form is crop-specific, a value of zero is acceptable when the crop is not in season; however, use of a zero should be explained.

 $\begin{array}{l} \mbox{Million Gals/Mo} = Lw_{(c)} \mbox{ in/mo x } \_ ac \div 12 \mbox{ in/ft x 43,560 ft}^2/ac \ x \ 7.481 \ gals/ft^3 \div 1,000,000 \\ (\mbox{Enter and use the number of acres for the crop type being irrigated}) \end{array}$ 

| Month | Days/Mo       | ET<br>(in/mo) | P<br>(in/mo) | Lw <sub>(c)</sub><br>(in/mo) | M Gals/Mo                                             | MGD                                   |
|-------|---------------|---------------|--------------|------------------------------|-------------------------------------------------------|---------------------------------------|
| Jan   | 31            |               |              |                              |                                                       |                                       |
| Feb   | 28            |               |              |                              |                                                       |                                       |
| Mar   | 31            |               |              |                              |                                                       |                                       |
| Apr   | 30            |               |              |                              |                                                       |                                       |
| May   | 31            |               |              |                              |                                                       |                                       |

## WTS-1B: APPENDIX TWO

## NITROGEN LOADING LIMIT WORKSHEET

The nitrogen loading equation takes into account precipitation, evapotranspiration, plant nitrogen uptake, nitrogen content of the applied effluent, nitrogen denitrification and volitilization in the soils, and allowable percolate nitrogen concentration. The equation included below is from <u>Wastewater</u> <u>Engineering: Treatment, Disposal, and Reuse</u>, (Metcalf and Eddy, 1991)

 $Lw_{(n)} = \underline{[(Cp, mg/l) x (P-ET, in/yr)] + [(U, lb/acre-yr) x (4.4)]}_{[(1-f) x (Cn, mg/l)] - (Cp, mg/l)}$ 

where:

 $Lw_{(n)}$  = Allowable Hydraulic Loading Rate Based on Nitrogen Loading rate (in/yr);

Cp = Total Nitrogen Concentration in Percolating Water (mg/l);

ET = Evapotranspiration Rate (in/yr);

P = Precipitation Rate (in/yr);

U = Nitrogen Uptake Rate by Crop (lb/acre-yr);

4.4 = Combined Conversion Factor;

Cn = Total Nitrogen Concentration in Applied Wastewater (mg/l); and

f = Fraction of Applied Total Nitrogen Removed by Denitrification and Volatilization.

#### "Cp" - Nitrogen in Percolating Water

A conservative value for Total N in the water that percolates past the root zone (Cp) is 7 mg/l, which is the first "red flag" value for Nitrate as N in monitoring well samples. Setting the Cp limit at a constant value aids in obtaining an hydraulic nitrogen loading rate  $(Lw_{(n)})$  which should be protective of groundwater resources. The drinking water standard for Nitrate as N is 10 mg/l, which would be the maximum allowable value for Cp.

#### "ET" - Evapotranspiration

Evapotranspiration is defined as the "loss of water from the soil both by evaporation and by transpiration from the plants growing thereon" (Websters Dictionary, 1990). Since different plants transpire at different rates, a crop coefficient (Kc) can be used to modify the potential ET for a particular area. Values for Kc vary depending upon the geographical location of the crop, and the species grown. If a crop coefficient can be determined, when multiplied by the potential ET rate, the result is a more accurate estimate of ET for an irrigation site. The Division recommends that reusers contact local agriculture representatives identified in Appendix Five for further crop-specific and regional information.

#### "U" - Crop Nitrogen Uptake

Plant nitrogen uptake rates (U) are crop-specific, and can be obtained from the local Extension Service, literature, or other reputable sources. Using the accepted value for U in this equation assumes that the harvested portion of the crop is removed from the site. If plant cuttings are not removed from the area, then the amount of nitrogen removed by uptake should be offset by the amout of nitrogen returned to the soil by decomposing cutting materials. If alfalfa, or another legume, is the site's crop, then similar considerations should be made for atmospheric nitrogen which is fixed into the soil by alfalfa. A discussion with the local agricultural extension service is recommended prior to finalizing a "U" value.

WTS-1B: Appendix Two Page 2

#### "Cn" - Nitrogen in Applied Wastewater

The total nitrogen in the applied effluent water (Cn) can be obtained from the treatment plant that is supplying the effluent. For site design, an average value can be used. For completion of the required annual balance report, the actual analytical results from Discharge Monitoring Reports shall be used.

#### "f" - Nitrogen lost to Denitrification and Volatilization

The amount of nitrogen lost to denitrification and volatilization varies depending upon the nitrogen characteristics of the applied wastewater and the microbial activity in the soil. Microbial denitrification, in soils with a sufficient carbon source for the biological activity, may account for as much as 15 to 25 percent of the applied nitrogen during warm, biologically active months. Volatilization of ammonia may be as much as 10 percent, depending upon the ammonia fraction in the total nitrogen applied. (Metcalf & Eddy, 1991) For arid climates, such as Nevada, the value typically used for the "f" term is 0.2.

#### Nitrogen Addition by Chemical Fertilizers

If the allowable reuse water application volume is limited by plant consumptive use (Worksheet 1-A), nitrogen may need to be added by commercial fertilizer. In the design of a reuse site, and preparation of an EMP, this should be estimated to provide the site operator with a guideline for fertilizer application, in addition to the nitrogen being applied via the treated effluent. The application of fertilizer must then be incorporated into the required annual report to demonstrate that the application of commercial nitrogen and effluent nitrogen did not exceed the plant crop's uptake rate.

<u>Worksheet 2-C</u> is designed to be used to provide the Division with the required annual report of effluent and fertilizer usage. Reuse permits require that the annual evaluation of the effluent application include, "the total nitrogen in the applied wastewater, nitrogen from fertilizer applications, nitrogen uptake by plant materials, evapotranspiration rate, precipitation rate, and fraction of applied nitrogen removed by denitrification and volatilization." While Worksheet 2-C does not take precipitation and evapotranspiration into account, the permittee should compare each year's P and ET rates to those that were used during the site design and EMP preparation phases to ensure that the original assumptions remain valid.

Worksheet 2-C can also be utilized as a site management tool to *estimate* the amount of commercial fertilizer which may be required in an upcoming month. However, use of the worksheet in this manner does not preclude the responsible use of good irrigation and nutrient management practices.

## Worksheet 2-A

#### WATER REQUIREMENT DESIGN WORKSHEET: Maximum Hydraulic Loading Rate Based On Annual Nitrogen Balance Evaluation

| Page _              | of Crop Type =                                                                                                             |
|---------------------|----------------------------------------------------------------------------------------------------------------------------|
| Lw <sub>(n)</sub> = | $= \frac{[Cp x (P-ET)] + (U x 4.4)}{[(1-f) x Cn] - Cp}$                                                                    |
| (A)                 | Total Nitrogen in Percolating Water (Cp, mg/l) =                                                                           |
| (B)                 | Annual Precipitation (P, in/yr) =                                                                                          |
| (C)                 | Annual Evapotranspiration (ET, in/yr) =                                                                                    |
|                     | (Multiply by Crop Coefficient (Kc) if value is known)                                                                      |
| (D)                 | (B) - (C) = (in/yr) (Note: In Nevada, P is less that ET; therefore a negative number is correct to use in this worksheet.) |
| (E)                 | (A) x (D) =                                                                                                                |
|                     |                                                                                                                            |
| (F)                 | Crop Nitrogen Uptake (U, lb/ac-yr) =                                                                                       |
| (G)                 | (F) x 4.4 =                                                                                                                |
| (H)                 | (E) + (G) =                                                                                                                |
| (I)                 | Fraction of Applied Total Nitrogen Lost to Denitrification and Volatilization (f) =                                        |
| (J)                 | 1- (I) =                                                                                                                   |
| (K)                 | Total Nitrogen in Applied Effluent (Cn, mg/l) =                                                                            |
| (L)                 | (J) x (K) =                                                                                                                |
| (M)                 | (L) - (A) =                                                                                                                |
| (N)                 | (H) $\div$ (M) = Lw <sub>(n)</sub> (inches/year) =                                                                         |

If the Water Use Rate calculated in ("N") above is the lowest application volume calculated for the annual Consumptive Use Limit (Worksheet 1-A) or the Nitrogen Limit (This Worksheet), then fill out Worksheet 2-B to estimate the planned maximum daily flow for the site.

### Worksheet 2-B

#### WATER REQUIREMENT DESIGN WORKSHEET: Maximum Hydraulic Loading Rate Based On Annual Nitrogen Balance Evaluation

Page \_\_\_\_\_ of \_\_\_\_\_ Crop Type = \_\_\_\_\_

 $Lw_{(n)} = \underline{[Cp \ x \ (P-ET)] + (U \ x \ 4.4)}_{[(1-f) \ x \ Cn]} - Cp$ 

Monthly values for evapotranspiration are dependent on the crop type and regional area of the site, as well as the crop coefficient if known. Monthly precipitation is also regional. The values for ET and P can be obtained from the local extension service, literature, or other reputable sources. Please see the explanation in the "WTS-1B: Appendix Two" text for futher discussion of crop coefficients.

The monthly value of the crop nitrogen uptake (U) can be calculated according to the equation included on the Table. Please see the discussion in the "WTS-1B: Appendix Two" text regarding "U" values for alfalfa crops or sites that do not remove crop cuttings. If a different distribution of monthly "U" is used, due to circumstances such as germination or dormancy periods, then provide documentation explaining the difference.

To calculate the monthly value for  $Lw_{(n)}$ , perform the calculation for each month as outlined in Worksheet 2-A, using the monthly values for "U", "P", "ET", and "Cn", and input the result in the table below. Since this form is crop-specific, a value of zero is acceptable when the crop is not in season; however, use of a zero should be explained.

Monthly U (lb/ac-mo) = U (lb/ac-yr) x ET(in/mo)  $\div$  ET (total in/yr)

| Month | Days/Mo | P<br>(in/mo) | ET<br>(in/mo) | U<br>(lb/ac-mo) | Lw <sub>(n)</sub><br>(in/mo) | M Gals/Mo                                                           | MGD<br>of Reclm'd<br>Water |

| Dec   | 31      |                                 |                                       |                                       |                                     |                                       |                                                      |
|       | I       |                                 |                                       | <b>I</b>                              |                                     | Total** =                             |                                                      |

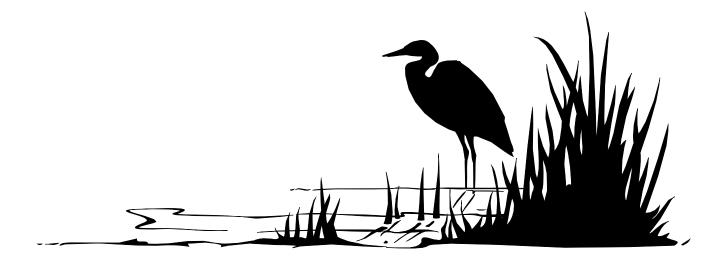

The Total N Applied to the crop should be less than the crop's Nitrogen Uptake Requirement. Please see your permit for directions if it is not.

## **APPENDIX THREE**

## WORKER HYGIENE FACT SHEETS

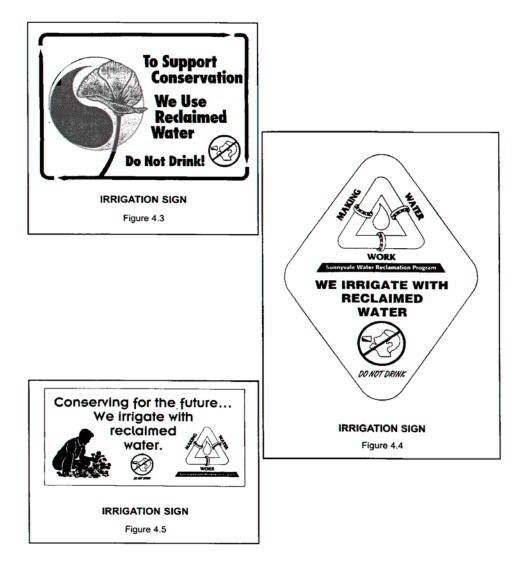

This project area uses reclaimed wastewater for irrigation. This reclaimed wastewater comes from the sewage treatment plant and meets the standards required for this level of reuse. Potential risks of disease transmission from the use of the reclaimed water is low, however, some general guidelines (listed below), should be followed protect you from becoming ill when working with reclaimed water:

- 1. Do not drink the reclaimed water or use the reclaimed water for washing.
- 2. Always wash hands and face with clean water and soap before eating, smoking, or drinking.
- 3. Wear rubber gloves when working on the irrigation system.
- 4. Try to keep the irrigation water off your skin and clothes as much as possible.
- 5. Always treat cuts immediately before continuing with work on the irrigation system.
- 6. Make sure the area is clear of people that may get sprayed before running the irrigation system.
- 7. Report any problems to your supervisor that you feel could pose a risk.

### APPENDIX SIX

### NEVADA ADMINISTRATIVE CODE - REUSE REGULATIONS

### Use of Treated Effluent for Irrigation

#### **Use of Treated Effluent**

NAC 445A.274 Definitions. (NRS 445A.425) As used in NAC 445A.274 to 445A.280, inclusive, unless the context otherwise requires, the words and terms defined in NAC 445A.2741 to 445A.2748, inclusive, have the meanings ascribed to them in those sections.

(Added to NAC by Environmental Comm'n by R063-04, eff. 10-6-2004)

NAC 445A.2741 "Area of use" defined. (NRS 445A.425) "Area of use" means a site, or an area of land, where treated effluent is in use pursuant to <u>NAC 445A.274</u> to <u>445A.280</u>, inclusive. (Added to NAC by Environmental Comm'n by R063-04, eff. 10-6-2004)

NAC 445A.2742 "Buffer zone" defined. (<u>NRS 445A.425</u>) "Buffer zone" means a bounded area adjacent to, and surrounding, an area of use, that is subject to the provisions of <u>NAC 445A.2756</u>. (Added to NAC by Environmental Comm'n by R063-04, eff. 10-6-2004)

NAC 445A.2743 "Graywater" defined. (NRS 445A.425) "Graywater" has the meaning ascribed to it in NAC 444.7616.

(Added to NAC by Environmental Comm'n by R063-04, eff. 10-6-2004)

NAC 445A.2744 "Impoundment" defined. (<u>NRS 445A.425</u>) "Impoundment" means a lake, reservoir or lined holding basin. (Added to NAC by Environmental Comm'n by R063-04, eff. 10-6-2004)

NAC 445A.2745 "Spray irrigation" defined. (<u>NRS 445A.425</u>) "Spray irrigation" means irrigation using sprinklers that are located above the ground surface. (Added to NAC by Environmental Comm'n by R063-04, eff. 10-6-2004)

NAC 445A.2746 "Subsurface irrigation" defined. (<u>NRS 445A.425</u>) "Subsurface irrigation" means irrigation using an underground distribution system. (Added to NAC by Environmental Comm'n by R063-04, eff. 10-6-2004)

NAC 445A.2747 "Surface irrigation" defined. (<u>NRS 445A.425</u>) "Surface irrigation" means irrigation using a flood irrigation system or a drip irrigation system. The term does not include spray irrigation. (Added to NAC by Environmental Comm'n by R063-04, eff. 10-6-2004)

NAC 445A.2748 "Treated effluent" defined. (<u>NRS 445A.425</u>) "Treated effluent" means sewage that has been treated by a physical, biological or chemical process. The term does not include graywater. (Added to NAC by Environmental Comm'n by R063-04, eff. 10-6-2004)

**NAC 445A.2749 Limitation on meaning of "agricultural purposes."** (<u>NRS 445A.425</u>) For the purposes of <u>NAC 445A.274</u> to <u>445A.280</u>, inclusive, the term "agricultural purposes" does not include the growing of crops for human consumption.

(Added to NAC by Environmental Comm'n by R063-04, eff. 10-6-2004)

#### NAC 445A.275 General requirements and restrictions. (NRS 445A.425)

- 1. A person shall not use treated effluent unless:
- (a) The person has:
  - (1) Received the approval of the Division of a plan for the management of effluent; and
  - (2) Obtained a permit pursuant to NAC 445A.228 to 445A.263, inclusive; and
- (b) The treated effluent has received at least secondary treatment.
- 2. As used in this section:

(a) "Five-day inhibited biochemical oxygen demand" means the amount of dissolved oxygen required to stabilize the carbonaceous decomposable organic matter by aerobic bacterial action at 20 degrees centigrade for 5 days.

(b) "Plan for the management of effluent" means:

(1) An effluent management plan; or

(2) A site specific management plan.

(c) "Secondary treatment" means the treatment of sewage until the sewage has, calculated as a 30-day average:

(1) A 5-day inhibited biochemical oxygen demand concentration of 30 milligrams per liter or less;

(2) A total suspended solids concentration of 30 milligrams per liter or less; and

(3) A pH of 6.0 to 9.0 SU.

(Added to NAC by Environmental Comm'n, eff. 9-13-91; A by R063-04, 10-6-2004)

### NAC 445A.2752 Signs: Required placement and contents. (NRS 445A.425)

1. A person using treated effluent shall post signs along the outer perimeter of the:

- (a) Area of use; and
- (b) Buffer zone, if any.
- 2. The signs must provide reasonable notice to the general public that:
- (a) Treated effluent is in use; and
- (b) Contact with the effluent should be avoided.

(Added to NAC by Environmental Comm'n by R063-04, eff. 10-6-2004)

### NAC 445A.2754 Irrigation: Requirements and restrictions. (NRS 445A.425)

1. A person using treated effluent for irrigation shall not:

(a) Allow the effluent to run off the site being irrigated.

(b) Except as otherwise provided in <u>NAC 445A.2768</u>, use treated effluent to irrigate crops intended for human consumption.

2. A person using treated effluent for spray irrigation shall conduct the irrigation in a manner that inhibits the treated effluent spray from drifting beyond the area of use or the buffer zone, if any.

(Added to NAC by Environmental Comm'n by R063-04, eff. 10-6-2004)

#### NAC 445A.2756 Buffer zones: Size; boundaries; restriction. (NRS 445A.425)

1. Except as otherwise provided in <u>NAC 445A.2766</u>, <u>445A.2768</u> and <u>445A.2771</u>, the Division will establish the size of a buffer zone.

2. The inner boundary of a buffer zone is determined by measuring a distance equal to the size of the buffer zone from:

(a) A boundary line of the property on which the site is located;

(b) A sign posted pursuant to <u>NAC 445A.2752</u> informing the public of the presence of treated effluent; or

(c) Any point where the property is open to public access, as determined by the Division.

3. Except as otherwise provided in <u>NAC 445A.2754</u>, a buffer zone must be kept free of treated effluent. (Added to NAC by Environmental Comm'n by R063-04, eff. 10-6-2004)

# NAC 445A.276 Reuse categories: Requirements for bacteriological quality of effluent. (<u>NRS</u> <u>445A.425</u>)

1. Treated effluent being used for an activity approved for a reuse category must meet the following requirements for bacteriological quality for that category:

|                         | Total Coliform       |     | Fecal C     | Coliform  |          |
|-------------------------|----------------------|-----|-------------|-----------|----------|
|                         | c.f.u. or mpn/100 ml |     | c.f.u. or n | npn/100ml |          |
| Reuse Category          | А                    | В   | С           | D         | Е        |
| 30-day geometric mean   | 2.2                  | 2.2 | 23          | 200       | No Limit |
| Maximum daily<br>number | 23                   | 23  | 240         | 400       | No Limit |

2. As used in this section, "c.f.u. or mpn/100ml" means colony forming units or most probable number per 100 milliliters of the treated effluent.

(Added to NAC by Environmental Comm'n, eff. 9-13-91; A by R063-04, 10-6-2004)

**NAC 445A.2762 Reuse category A: Approved uses.** (<u>NRS 445A.425</u>) Treated effluent that meets the requirements for bacteriological quality set forth in <u>NAC 445A.276</u> for reuse category A may be used for:

- 1. Spray irrigation of land used as a cemetery, commercial lawn, golf course, greenbelt or park even if:
- (a) Public access to the area of use is not controlled; and
- (b) Human contact with the treated effluent can reasonably be expected to occur.
- 2. An impoundment in which swimming is prohibited even if:
- (a) Public access to the impoundment is not controlled; and
- (b) Human contact with the treated effluent can reasonably be expected to occur.
- 3. Any activity approved for reuse category B, C, D or E.
- 4. Any other use that is approved by the Division.

(Added to NAC by Environmental Comm'n by R063-04, eff. 10-6-2004)

**NAC 445A.2764 Reuse category B: Approved uses.** (<u>NRS 445A.425</u>) Treated effluent that meets the requirements for bacteriological quality set forth in <u>NAC 445A.276</u> for reuse category B may be used for:

- 1. Spray irrigation of land used as a cemetery, commercial lawn, golf course, greenbelt or park if:
- (a) Public access to the area of use is controlled; and
- (b) Human contact with the treated effluent cannot reasonably be expected to occur.
- 2. Subsurface irrigation of land used as a commercial lawn, greenbelt or park.
- 3. Cooling water in an industrial process.

4. Fire-fighting operations in an urban area if approved by the fire department, fire protection district or other fire-fighting agency in whose district the fire occurs.

- 5. Any activity approved for reuse category C, D or E.
- 6. Any other use that is approved by the Division.

(Added to NAC by Environmental Comm'n by R063-04, eff. 10-6-2004)

# NAC 445A.2766 Reuse category C: Approved uses. (NRS 445A.425)

1. Treated effluent that meets the requirements for bacteriological quality set forth in <u>NAC 445A.276</u> for reuse category C may be used for:

(a) Spray irrigation of land used as a cemetery, golf course or greenbelt if:

(1) Public access to the area of use is controlled;

- (2) Human contact with the treated effluent does not occur; and
- (3) A buffer zone of not less than 100 feet is maintained.
- (b) Watering of nursery stock if public access to the area of use is controlled.
- (c) Establishment, restoration or maintenance of a wetland if public access to the wetland is controlled.
  - (d) Washing of gravel used in concrete mixing.
  - (e) Feed water for a boiler.
  - (f) An impoundment if:
    - (1) Public access to the impoundment is controlled; and
    - (2) Human contact with the treated effluent cannot reasonably be expected to occur.
- (g) Fire fighting of forest or other wildland fires if approved by the fire department, fire protection district or other fire-fighting agency in whose district the fire occurs.
  - (h) Any activity approved for reuse category D or E.
  - (i) Any other use that is approved by the Division.
  - 2. As used in this section:
  - (a) "Nursery stock" has the meaning ascribed to it in <u>NRS 555.23562</u>.
  - (b) "Wetland" has the meaning ascribed to it in <u>NRS 244.388</u>.
  - (Added to NAC by Environmental Comm'n by R063-04, eff. 10-6-2004)

# NAC 445A.2768 Reuse category D: Approved uses. (NRS 445A.425)

1. Treated effluent that meets the requirements for bacteriological quality set forth in <u>NAC 445A.276</u> for reuse category D may be used for:

(a) Spray irrigation of land used for agricultural purposes if:

- (1) Public access to the area of use is prohibited; and
- (2) A buffer zone of not less than 400 feet is maintained.
- (b) Surface irrigation of land used:
  - (1) As greenbelt if:
    - (I) Public access to the area of use is prohibited; and
    - (II) Human contact with the treated effluent does not occur.
  - (2) For agricultural purposes; and
  - (3) For the cultivation of fruit-bearing trees or nut-bearing trees.
- (c) Subsurface irrigation of land used for agricultural purposes if public access is controlled.
- (d) Dust control.
- (e) Soil compaction.
- (f) Flushing sewer lines.
- (g) An impoundment if:
  - (1) Public access to the impoundment is prohibited;
  - (2) All human activities involving contact with the treated effluent are prohibited; and
  - (3) Human contact with the treated effluent does not occur.
- (h) Any activity approved for reuse category E.
- (i) Any other use approved by the Division.

2. As used in this section, "dust control" means the program required pursuant to <u>NAC 445B.22037</u> to prevent controllable particulate matter from becoming airborne.

(Added to NAC by Environmental Comm'n by R063-04, eff. 10-6-2004)

**NAC 445A.2771 Reuse category E: Approved uses.** (<u>NRS 445A.425</u>) Treated effluent that meets the requirements for bacteriological quality set forth in <u>NAC 445A.276</u> for reuse category E may be used for:

1. Spray irrigation of land used for agricultural purposes if:

(a) Public access to the area of use is prohibited; and

(b) A buffer zone of not less than 800 feet is maintained.

2. Any other use that is approved by the Division.

(Added to NAC by Environmental Comm'n by R063-04, eff. 10-6-2004)

NAC 445A.279 Determining quality of effluent: Storage reservoirs excluded from treatment process. (NRS 445A.425) For the purpose of determining the quality of effluent, storage reservoirs do not constitute part of the treatment process.

(Added to NAC by Environmental Comm'n, eff. 9-13-91)—(Substituted in revision for NAC 445.178)

**NAC 445A.280 Waiver or modification of requirements.** (<u>NRS 445A.425</u>) The Director may waive compliance with or modify any requirement of <u>NAC 445A.274</u> to <u>445A.280</u>, inclusive, for a specific proposed use of treated effluent upon his determination that because of the size, type or location of the proposed use, the waiver or modification is consistent with the policy set forth in <u>NRS 445A.305</u>.

(Added to NAC by Environmental Comm'n, eff. 9-13-91; A by R063-04, 10-6-2004)

SPECIAL COMMENTS

105, IN POUNDS/ACRE.

FOR ABOVE

THE BULK DENSITY OF THE SOIL DETERMINES THE FACTOR WHICH CONVERTS PPM INTO LDS/ACRE. BELOW ARE LISTED THE BULK DENSITIES AND CONVERSION FACTORS: SAMPLE ID 7B3 BULK DENSITY 1.4 CONVERSION FOTR 2.0 TO INCREASE EFFICIENCY, NITROGEN SHOULD BE SPLIT INTO MULTIPLE APPLICATIONS.

### **1.0 INTRODUCTION**

Lahontan Regional Water Quality Control Board (Lahontan) informed the South Tahoe Public Utilities District (STPUD) that an Assimilative Capacity Model must be completed as an element of the South Tahoe Public Utilities District Diamond Valley Ranch Nutrient Management Plan (NMP). As such, Wood Rodgers Inc. was directed by STPUD to prepare the model.

In their Assimilative Capacity Staff Report, Lahontan defines assimilative capacity as "the ability of a [ground] water body to receive and accommodate natural and anthropogenic sources of pollutants (from point and non-point sources), while maintaining water quality standards that are protective of the beneficial uses of the water resource." Specifically, it is the ability of the receiving groundwater to absorb nutrients without excessively taxing the receiving water. Several factors can affect the assimilative capacity of a groundwater basin, including input nutrients/contaminants to the existing systems such as with treated wastewater, soil type, and background groundwater chemistry.

This technical report was prepared at the request of STPUD and is intended to outline the procedure used to address the assimilative capacity of the groundwater at the Diamond Valley Ranch (DVR).

### 2.0 REGULATORY REQUIREMENTS

At present there are no regulatory requirements for users to prepare either Nutrient Management Plans or Assimilation Capacity models for the reuse of treated wastewater for agricultural irrigation. However, the State Water Quality Control Board is in the process of developing such regulations and associated requirements for planning and reporting.

STPUD and Wood Rodgers were provided with the "Staff Report: Assimilative Capacity Workshop" (Lahontan) as a means to prepare the requested Assimilation Capacity Model. The staff report did not provide guidance on how to develop the model, nor did it outline Lahontan's requirements for model variables.

The goal of the Assimilative Capacity Workshop, was to give the board "a better understanding of the factors that should be evaluated in making decisions within the context of Resolution No. 68-16" (Lahontan). This resolution, entitled *Statement of Policy with Respect to Maintaining High Quality of Waters in California,* is commonly referred to as the Nondegradation Policy and it was adopted in 1968. As a result, Lahontan established a non-degradation objective in their Basin Plan.

The factors that Lahontan must consider when adopting water quality objectives are listed in the Porter-Cologne Water Quality Control Act and they were summarized in the staff report. The factors include: past, present, and probable future beneficial uses of the water; environmental characteristics of the hydrographic unit under consideration and its water quality; water quality conditions that could reasonably be achieved through the coordinated control of all factors which affect water quality in the area; economic considerations; the need for developing housing in the region; and, the need to develop and use recycled water.

The purpose of developing the model was to determine (1) whether irrigating with reclaimed water would degrade the receiving groundwater, and (2) how many years it would take to exceed a specific threshold if degradation was in fact observed.

### **3.0 METHODS**

In order to develop the requested model, water quality data for three reclaimed water irrigation locations in Carson Valley, Nevada, were collected from the Nevada Department of Environmental Protection (NDEP). Wood Rodgers had copies of an approved Effluent Management Plan (EMP) for each of these sites in, so the corresponding Discharge Monitoring Report (DMR) data was requested. For each site, the initial total nitrogen concentration of the applied reclaimed water was noted and quarterly water quality data (nitrate concentration) from on-site monitoring wells was examined. The applied reclaimed water flow rate was also noted.

The intent of examining the existing data was to determine whether a degradation of the groundwater was occurring as a result of the reclaimed water irrigation. This method was the best possible approach since it utilized sitespecific, empirical data. A predictive model, developed from various assumptions, would not provide the same level of confidence as the actual site data.

### 4.0 ANALYSIS

The data was evaluated for the three locations, but the data was limited. The nitrate concentration of the groundwater at the Park Land and Cattle Company Property (Table 1) did not increase above the permitted maximum as a result of reclaimed water irrigation. The recorded groundwater nitrate concentrations appeared to fluctuate randomly from quarter to quarter and the concentrations of nitrate in the groundwater did not appear to be related to the concentration of total nitrogen in the applied reclaimed water.

Table 1. DMR data for Park Land and Cattle Co. Property, Permit NEV2003500

Data from the other two sites was also evaluated. There was no reclaimed water irrigation reported on the DMRs, so the determination of a possible relationship could not be completed.

We can only hypothesize, at this point, based on the Park Land and Cattle Data, that there is no cumulative effect. There were only two quarters where effluent was used (the actual flows of 0.73 MGD and 1.48 MGD were recorded on the DMR) and no significant increase in groundwater nitrate concentration was observed over a six-quarter period.

If requested by Lahontan, future work could occur directly with NDEP. Information could be provided as to which site(s) had the longest history/duration of effluent irrigation and a similar analysis on that data could be undertaken since it would be more representative of the long-term. Additionally, since baseline data already exist for the DVR, post-irrigation empirical data could be collected and evaluated in order to verify that there is no cumulative effect as Wood Rodgers initially hypothesized.

### 5.0 FINDINGS

Because no trend could be observed that correlated the concentration of nitrate in the receiving groundwater to the concentration of nitrate in the applied reclaimed water, the type of predictive model requested by Lahontan could not be created. As a result, the methods required for an Effluent Management Plan, as outlined in Metcalf and Eddy (1991), were used to determine the maximum amount of reclaimed water that could be applied as irrigation on the Diamond Valley Ranch.

The "nitrogen loading" determination (Metcalf and Eddy 1991) accomplishes the same goal as an assimilation capacity model, but in a different manner. It is a better method because the "nitrogen loading" determination allows one to precisely determine the amount of reclaimed water that can be applied, given the nitrogen concentration of the reclaimed water, the threshold nitrate concentration for the receiving water, the specific crop (alfalfa fixes nitrogen and more reclaimed water can be applied compared to pasture grass), and the climate conditions (evapotranspiration and precipitation).

In order to determine the maximum allowable application rate, three distinct irrigation balances are required (plant consumptive use, nitrogen loading, and soil permeability) to be calculated in order to determine the limiting hydraulic loading rate. The assumed beneficial use of the groundwater is drinking water supply; therefore the maximum allowable nitrate concentration should be 10 mg/l, which is the current MCL for nitrate. As is common practice in developing a Nevada (EMP), a "red-flag" threshold level of 7 mg/l was set to insure that the receiving groundwater resource would not be excessively degraded to a point where it was no longer useable. A lower number could be used if an additional factor of safety was desired. This work is detailed in the Diamond Valley Ranch Nutrient Management Plan.

Because no cumulative effect was observed in the recorded data, Wood Rodgers has concluded that the assimilative capacity of receiving waters will not be impacted when irrigated with current STPUD recycled water, and a predictive degradation model would not be necessary. The accepted practice of using the three distinct irrigation balances to determine the limiting hydraulic loading rate is adequate because of the "nitrogen loading" determination, which allows the reuser to set the threshold and calculate the total amount of reclaimed water that can be applied before they theoretically reach that specified threshold number.

It is our professional opinion that the only way to truly observe the presence or absence of cumulative effects is to determine the existing (pre-irrigation) baseline concentrations of nutrients in the groundwater (which STPUD already has collected), begin irrigating, monitor the groundwater for specific nutrients, and compare post-irrigation concentrations to pre-irrigation concentrations to determine if a trend exists. Continued monitoring while irrigating allows the reuser to track their site-specific effects and modify their irrigation plan as needed.

#### **INTRODUCTION**

This project is part of an overall effort to evaluate the water quality in Alpine County, California, specifically as it relates to the South Tahoe Public Utility District's (STPUD) treated effluent program.

In 2004, the Desert Research Institute (DRI) performed a study (DRI, 2004) that identified several wells with increasing nitrate concentrations. Nitrate in drinking water has been linked with methemoglobinemia (blue baby disease) in infants and chronic toxicity in adults, and pose a possible cancer risk (Shearer, *et al*, 1972; National Academy of Sciences, 1977; National Academy of Sciences, 1978). Several wells in Alpine County are approaching the current drinking water standard for nitrate of 10 mg/l as nitrogen.

Alpine County is interested in knowing the reason for the nitrate increase in these wells. Some potential sources of nitrate:

- Atmospheric deposition through dryfall, rainfall, and snowfall;
- Dissolution of nitrogen-bearing minerals;
- Animal waste;
- Fertilizer;
- Decomposing plant material;
- Human waste from septic systems;
- Human waste from treated wastewater effluent;

Alpine County is in the Sierra Nevada mountain Range in Northern California, south of Lake Tahoe, and bordering Nevada (Figure 1). Elevations range from over 10,000 ft (3050 m) to below 5,000 ft (1500 m) at the Nevada border. All surface water from to the treated effluent program drain northwest into the Carson River system. The West Fork of the Carson River and Indian Creek originate at high elevation where discharge is primarily snowmelt. The lower elevations support alfalfa crops and livestock. A complex series of ditches provides irrigation water for these ranches. These ditches carry water from natural streams as well as from the treated effluent from South Lake Tahoe.

#### GOAL

The over-arching goal of the monitoring program in Alpine County is to identify the source, or sources, of nitrogen contamination in these wells. Because identifying the sources with a high degree of confidence is an expensive, multi-step process, Alpine County, STPUD, and DRI decided to perform site visits and conduct interviews with well owners to determine if there are simple or likely reasons for the increasing trend in nitrate. The purpose of these site visits and interviews was to: 1) assess the quality of well construction; 2) speak with the well owners about typical land-use practices, including agricultural practices and septic system maintenance; 3) gather historical information about each well; and 4) to make recommendations for each well. This report is a summary of the information gathered from the site visits and interviews.

#### RESULTS

#### Reconnaissance

On July 5, 2006, DRI personnel accompanied STPUD on their groundwater sampling run. They visited each site to survey the landscape, take photographs of the well, and document the land uses in the area. If the well owner was home, they spoke with him/her to ask questions about the history of the well and land-use practices in the surrounding area. The following is a summary of the visit.

Six Alpine County wells have increasing nitrate concentrations. They are: GW-04, GW-05, GW-07, GW-08, GW-11, and ACMW-04W (Figure 1).

#### Summary for GW-04

#### Site Visit

As shown below in Figure 2, nitrate in GW-04 is increasing very slowly and there is little reason for concern. From 1994 to 1997, however, irrigation and grazing were allowed to occur next to the well. All recent measurements show nitrate levels below 1 mg/l, well below the nitrate drinking water standard of 10 mg/l. In spite of that fact, DRI spoke with the well owner by phone to gather data, followed by a site visit.

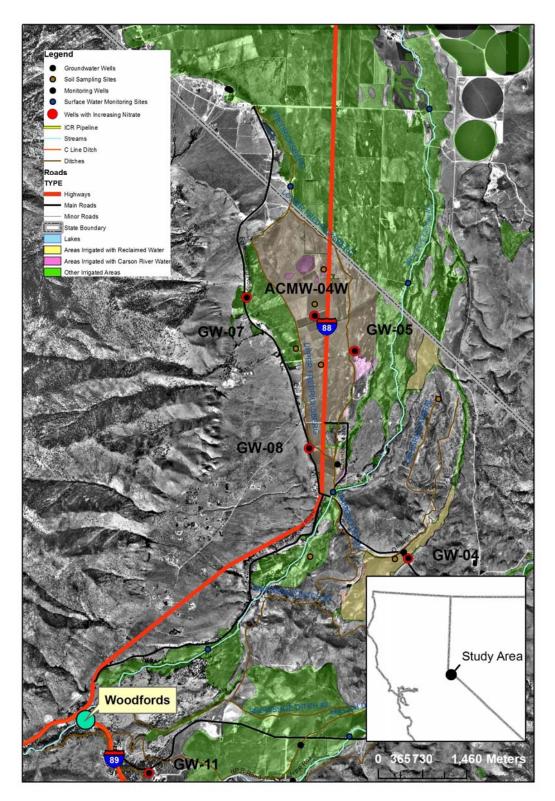

Figure 1. Location Map of wells with increasing nitrate concentrations.

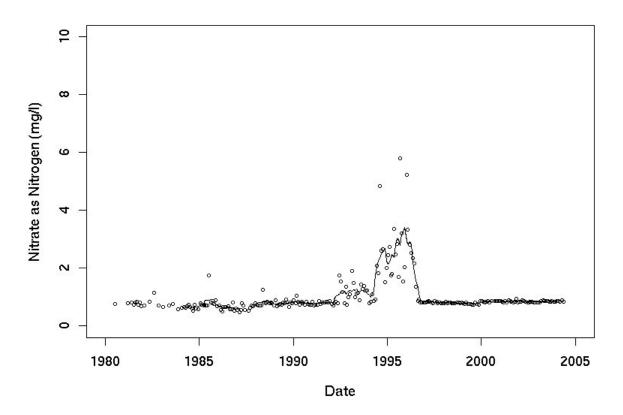

Figure 2. GW-04: Nitrate trend.

The well is directly behind the garage and is usually covered with a trash can to prevent freezing. The well was drilled in 1969 by Kawtcheck Drilling in Gardnerville, Nevada. There does not appear to be a surface seal. Grass is growing around the well and cattle are allowed to graze that area very rarely. The septic tank and leach field are approximately 300 feet north of the buildings (Figure 3). Groundwater flow in that area is generally south to north. A ditch carrying treated effluent (Figure 4) runs approximately 20 feet from the well.

Figure 3. GW-04: Septic tank and leach field.

Figure 4. GW-04: Effluent ditch.

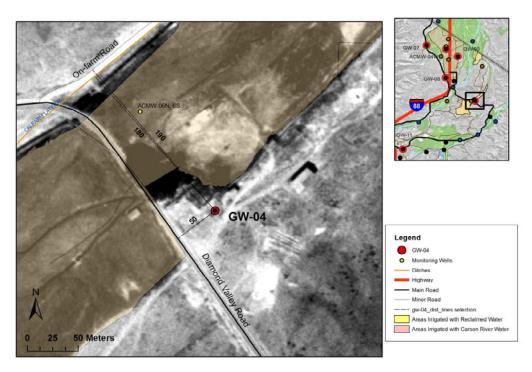

Figure 5. GW-04: Aerial photograph of property.

#### Recommendation

Though the increase in nitrate is statistically significant, it is increasing slowly and levels are well below the drinking water standard of 10 mg/l. However, there was a dramatic increase in nitrate concentration between 1994 and 1997. The well owner revealed that during that period, irrigation and grazing was allowed to occur next to the well. Since stopping that practice in 1998 the concentrations decreased significantly. Therefore, we recommend that the well owner refrain from irrigating or allowing cattle to graze near the well.

#### **Summary for GW-05**

#### Site Visit

Nitrate in well GW-05 has been increasing steadily since the mid-1980s (Figure 6). Recent concentrations are approximately 3.5 mg/l. The well is in the front yard (Figure 7). The owner stated that the well was drilled sometime before 1900. Drilling techniques are unknown, but there is no surface seal and the owners believe it is about 65 feet deep. A small ditch that carries treated effluent runs within two feet of the well. For many years, the yard and garden were flood-irrigated with this treated effluent from the ditch. Approximately eight years ago, the owners switched to a sprinkler system using water from the well, and the ditch is no longer used. The property has two septic tanks, one behind the main house and one behind the bunkhouse. Each is downgradient of the well.

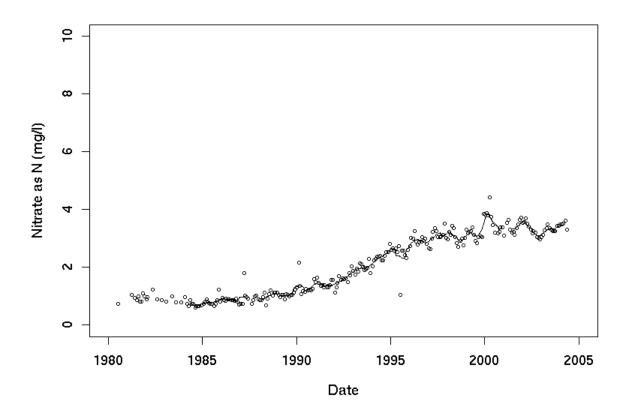

Figure 6. GW-05: Nitrate trend.

Figure 7. GW-05: Pump.

7

DRAFT: Investigation of the Sources of Increasing Nitrate in Groundwater to Alpine County, California

Irrigation and grazing occurs in all fields surrounding the property. Also, as shown in Figure 8, the Fredericksberg Ditch runs within 300 feet of the well. This is an unlined ditch, and seepage to the aquifer is likely to occur. As a result, it is possible the shallow well draws effluent from the ditch.

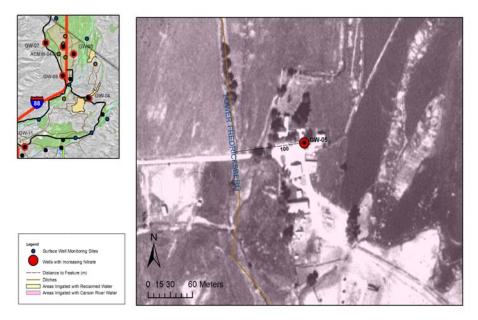

Figure 8. GW-05: Aerial photograph of property.

#### **Recommendation**

It is likely that some portion of water in this well is treated effluent that is recharging the shallow aquifer in the vicinity of the well, thereby allowing delivery of this contaminated water from the well to the household. Further evidence is that nitrate levels are higher in the summer months when lawn irrigation is occurring.

We recommend two options: 1) that the existing well be abandoned and a new, properly constructed well with a surface seal be drilled with adequate setback distances from septic leach fields and effluent ditches; or 2) because it appears that nitrate concentrations are leveling off to less than four mg/l (well below the drinking water standard of ten mg/l), continue monitoring until concentrations rise.

#### Summary for GW-07

#### Site Visit

The local groundwater flow direction in the aquifer beneath the property is likely west to east. Samples from the well show large fluctuations in nitrate levels, as well as a general increase over the past 20 years (Figure 9). Also, the high values associated with the wide fluctuations usually occur in the winter months. The well was drilled in the 1930s, does not have a surface seal, and is approximately 60 feet deep. Water from the well is used solely for domestic purposes. There is a submersible pump in the well that was replaced approximately five years ago. The septic tank is directly behind (east of) the house with a leach field approximately 150 feet farther east. The well is approximately 200 feet from the septic tank. The septic tank was replaced approximately seven years ago (though the property owner was not sure) and was pumped approximately four years ago. Examination of the trend shows a decrease in both nitrate levels and in the magnitude of the fluctuation approximately eight years ago. This is followed by a gradual increase in levels and fluctuation six years after installing the new tank.

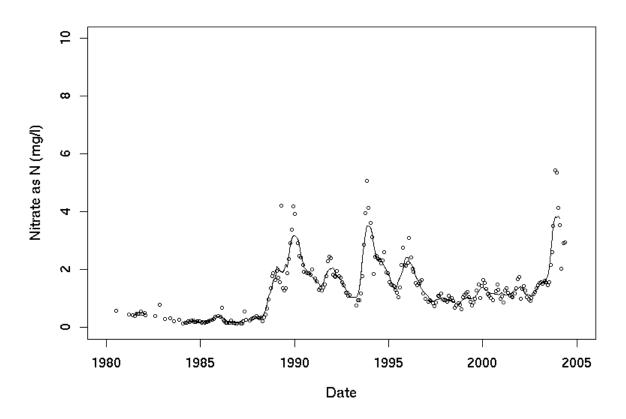

Figure 9. GW-07: Nitrate trend.

The surrounding fields (Figure 10) are irrigated with a blend of treated effluent and Carson River water, with the portion of effluent in the blend a function of the previous winter's snowpack. Cattle and horses are allowed to graze the fields.

Figure 10. GW-07: Irrigated area.

Given the scenario described above, the following facts were observed: 1) the septic tank is near the well; 2) higher levels of nitrate occur during the wet season (winter); 3) replacement of the tank appears to result in decreasing nitrate levels and fluctuations; and 4) six years after replacing the tank the nitrate concentrations and fluctuations start to increase. Also, STPUD reports coliform spikes in the winter at this well.

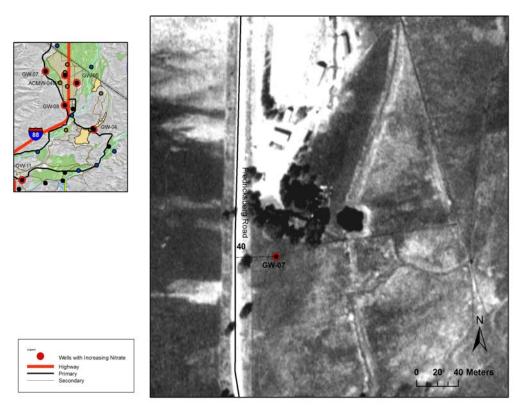

Figure 11. GW-07: Aerial photograph of property.

#### **Recommendation**

It is likely the septic system on the property is discharging untreated waste, resulting in nitrate and coliform contamination of the aquifer. It is therefore recommended that regular and frequent (every two to three years) pumping of the septic tank is conducted to prevent contamination of the well. The Environmental Protection Agency recommends that septic tanks be pumped every three to five years to properly maintain the system (EPA, 2005).

#### Summary for GW-08

#### Site Visit

Nitrate in GW-08 has been increasing steadily since 1987 with a short period of decrease from 1997 to 2000 (Figure 12). As with GW-07, nitrate levels are higher in the winter months than in the summer. Concentrations were above 8 mg/l in 1996 and 2002.

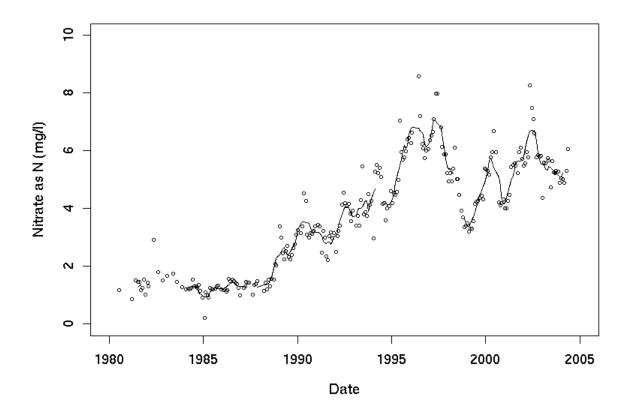

Figure 12. GW-08: Nitrate trend.

GW-08 sits at the base of the Carson Range, with groundwater likely moving from west to east. The Fredricksberg Ditch runs approximately 200 ft. east of the property (Figure 13). Both the tenants on the property and the property owner confirm the groundwater table is very close to the surface, at times resulting in ponding in the driveway. The well is approximately 100 ft. south of the living area (Figure 14) and is used for domestic purposes. The owner remembers that a new well drilled by Kawcheck drilling in Gardnerville about 20 years ago. During the site visit, the well was not located, but its location was confirmed by the owner. It is likely that a well drilled by a drilling company has a surface seal.

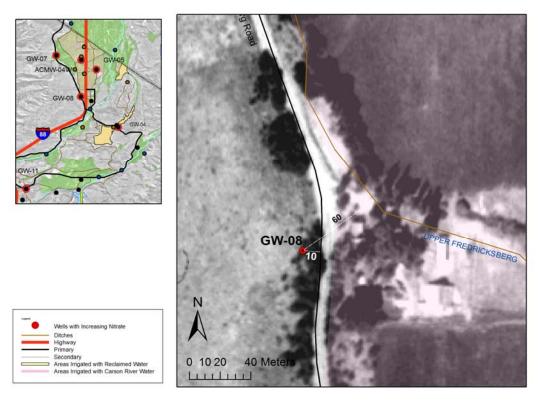

Figure 13. GW-08: Aerial photograph of property.

Figure 14. GW-08: Approximate location of well.

The septic tank is directly beneath the driveway and was last pumped about seven or eight years ago, according to the owner. The decrease in nitrate levels started about nine years ago. The septic tank has not been pumped since. Nitrate levels began increasing approximately three years after it was last pumped and continue to increase. It is possible the capacity of the septic tank is exceeded after three years of use (EPA, 2005). Neither the tenant nor the owner knew where the leach field was for the septic system.

All fields are irrigated with a blend of treated effluent and Carson River water.

#### Recommendation

It is likely the septic system is discharging untreated waste and contaminating groundwater. The shallow groundwater table (sometimes a few feet below the surface) is probably in direct contact with the overflowing septic effluent. Also, the concentration of nitrate being consumed by the tenants is getting close to the drinking water standards.

It is therefore recommended that regular and frequent (every two to three years) pumping of the septic tank be conducted to prevent overflow and contamination of the well. An engineered leach system may be required to properly dispose of septic effluent.

#### Summary for GW-11

#### Site Visit

Figure15 shows nitrate in well GW-11 increasing very slowly since 1993. Also, concentrations are much lower than the drinking water standard and not a cause for concern.

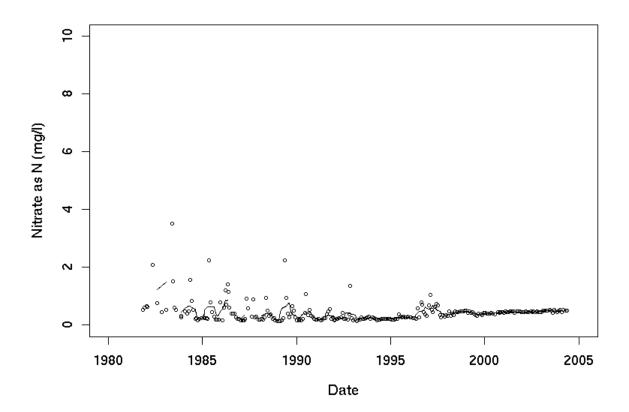

Figure 15. GW-11: Nitrate trend.

GW-11 is sampled from the spigot near the entrance to the school (Figure 16). Water from the well is used for all school activities and irrigation of the playing fields (Figure 17). Approximately eight years ago, a new 600-ft. well was drilled (Figure 18). The previous well was 150 ft. deep. The septic tank is approximately 200 to 300 ft. away from the well and is pumped yearly.

Figure 16. GW-11: Sampling location.

Figure 17. GW-11: Irrigated area.

Figure 18. GW-11: New well.

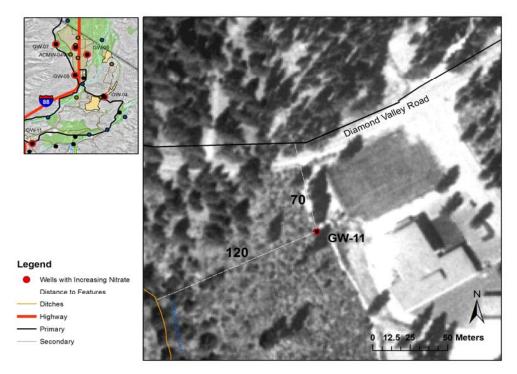

Figure 19. GW-11: Aerial photograph of property.

#### Recommendation

Though the concentration of nitrate in GW-11 is increasing, it is doing so very slowly. Also, concentrations are currently around 0.5 mg/l. Therefore, no action is needed.

### Summary for ACMW-04W

#### Site Visit

Figure 20 shows nitrate in well ACMW-04W increasing rapidly from 1988 to about 1996. After 1996 the concentrations decreased steadily. Present values are around 2 mg/l. The well appears to be well constructed and has a surface seal (Figure 21).

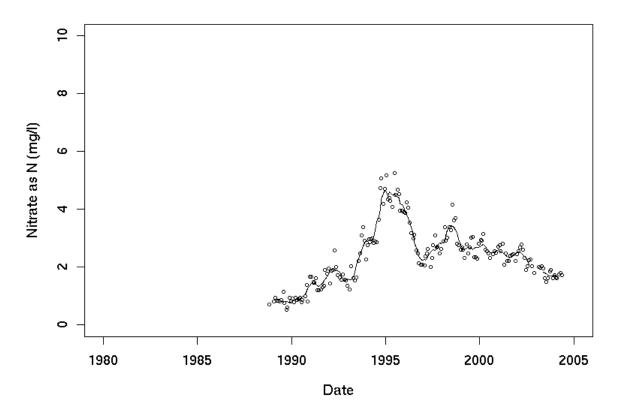

Figure 20. ACMW-04W: Nitrate trend.

Figure 21. ACMW-04W: Location

#### **Recommendation**

Because the concentration of nitrate has been decreasing consistently over the last 10 years, and levels are well below the drinking water standard of 10 mg/l, no action is needed.

#### SUMMARY OF RECOMMENDATIONS

- GW-04: Continue to restrict irrigation and grazing near the well.
- GW-05: Abandon the existing well and construct a new one with a surface seal, or continue monitoring until concentrations rise again.
- GW-07: Pump septic tank every two to three years.
- GW-08: Pump septic tank every two to three years and consider an engineered leach system because of high (near-surface) groundwater table.
- GW-11: No action.
- ACMW-04W: No action.
- Continue monitoring in all wells.

### ACKNOWLEDGEMENTS

The author thanks Dave Decker, Marjory Jones, Alan McKay, and Rina Schumer for reviewing this document.

## **1.0 INTRODUCTION**

In September 2007, Alpine County retained Alisto Engineering Group to review and evaluate the effectiveness of the recycled wastewater monitoring program of South Tahoe Public Utility District (STPUD) within Alpine County. The location of the project study area is shown on Figure 1.

## 1.1 Project Objectives

The objective of the study is to evaluate and determine the adequacy of the monitoring program in collecting data to assess the impact of using recycled wastewater for pasture crop irrigation on surface water, groundwater, and soil resources in Alpine County. The study is intended to modify/develop a monitoring program that will be effective in verifying and determining the impact of recycled wastewater application on regional and local groundwater quality within the land application area. As specified by Alpine County, the study includes developing recommendations for appropriate modifications to the existing monitoring network, including the proposed locations and standard construction of replacement or new groundwater monitoring wells to effectively evaluate the impact of recycled wastewater discharge on groundwater quality within the existing and future land application areas.

### 1.2 Scope of Work

The agreed scope of work for the evaluation of existing groundwater monitoring program included performing the following tasks in accordance with the protocol and procedures recommended by the various federal, state and local regulatory agencies, as well as generally accepted professional standards.

- 1. Collecting and compiling available reports and monitoring data pertinent to the recycled wastewater application program, including but not limited to: regional and site geology and hydrology, groundwater level measurements, current and proposed application areas, construction and boring logs for existing groundwater monitoring wells, and surveyed location of the monitoring wells.
- 2. Reviewing available data to determine the adequacy and effectiveness of the monitoring program in assessing the impact of recycled wastewater application at the existing and proposed irrigation areas focusing on the hydrogeology and groundwater flow patterns within the application areas rather than water quality impact.
- 3. Visual observing current and future wastewater application areas and inspecting the existing monitoring wells and potential locations for replacement and additional groundwater monitoring wells to determine site condition, accessibility, utility interferences, and other drilling constraints.
- 4. Surveying the existing groundwater monitoring wells by a licensed surveyor for horizontal and vertical controls (x, y, z coordinates) in reference to an established benchmark for use in evaluating and interpreting groundwater flow patterns and gradient.

- 5. Monitoring the water level at existing monitoring wells for four consecutive quarters to evaluate seasonal changes in groundwater level and prepare potentiometric surface map for interpretation of groundwater flow patterns during each monitoring event within the project or land application area.
- 6. Evaluating historical and recent water level data for use in interpreting groundwater flow direction and pattern and the hydrogeologic characteristics of the project area relative to the recycled wastewater monitoring program.
- 7. Determining the need for and location of additional monitoring points to effectively evaluate the impact of recycled wastewater application on groundwater and surface water quality.
- 8. Preparing this technical report to present the results of water level monitoring and evaluation of the recycled wastewater monitoring program, including recommended modifications to the existing monitoring network and specifications for construction of replacement or additional monitoring wells.

The results of the data compilation and interpretation of groundwater monitoring data are presented in this report in both tabular and graphical formats such as groundwater potentiometric contour maps and the proposed locations for replacement and additional monitoring wells are shown on maps.

#### 1.3 Project Background

Since the late 1960's, treated wastewater from STPUD has been exported and recycled for use as supplemental irrigation water in portions of Diamond Valley, Dutch Valley, and Wade Valley in Alpine County. Based on recommendations of an independent study by the US Department of Agriculture in 1980, the STPUD implemented a monitoring program to collect background groundwater and soil quality data at designated stations in 1981. Subsequently, the California Regional Water Control Board (RWQCB), Lahontan Region adopted the groundwater monitoring program as part of the RWQCB Order issued to STPUD in 1984.

In 1988, the STPUD installed nine shallow groundwater monitoring wells that were later included as part of the monitoring program. Five ditch monitoring stations were added into the monitoring program in 2003 as part of the agreement between the primary effluent users in California, primary tail-water users in Nevada and the Nevada Division of Environmental Protection (NDEP).

The RWQCB previously established the Waste Discharge Requirements (WDRs) for the STPUD wastewater treatment and discharge facility under Order No. 6-79-43, which was adopted on December 6, 1979. Subsequent updates to the WDRs included Order No. 6-84-24, adopted on February 9, 1984, Order No. 6-90-14, adopted on February 8, 1990, and Order No. 6-95-65 adopted on June 8, 1995.

In 2004, the RWQCB adopted Revised Order No. R6T-2004-0010 as an update to the WDR for the STPUD Wastewater Recycling Plant in South Lake Tahoe, El Dorado County and the wastewater application areas in Alpine County. Under Order No. R6T-2004-0010, the STPUD

Wastewater Recycling Plant and delivery system, Harvey Place Reservoir, and the Alpine County recycled wastewater conveyance system are referred to as the "Facility".

Treated wastewater from the STPUD Wastewater Recycling Plant is conveyed through an effluent export system to Harvey Place Reservoir, a man-made reservoir located between Diamond Valley Road and Indian Creek Reservoir approximately three miles southwest of Woodfords, California in Alpine County. Recycled wastewater is temporarily stored in Harvey Place Reservoir, which has a nominal capacity of approximately 3,800 acre-feet, before being discharged or released to a series of lined and unlined ditches that run through Diamond Valley, Wade Valley, and Carson Valley for delivery to various land application areas for pasture crop irrigation.

Treated wastewater is stored in Harvey Place Reservoir during the defined non-growing season (October 15 through April 1) and then released to the Diamond Ditch and Fredericksburg Ditch for conveyance to Alpine County Ranch Irrigation Systems where wastewater is used for irrigation of alfalfa and livestock grazing pastures. The Alpine County Ranch Irrigation Systems are operated under separate regulatory requirements for each individual user of recycled wastewater as stipulated by the RWQCB in the WDR. The RWQCB has authorized the use of recycled wastewater on approximately 2,000 acres in Wade Valley and Carson Valley in Alpine County.

Use of recycled wastewater is restricted by the Board Order to irrigation of seed and fiber crops, and fodder crops for non-milking animals. The Order also prohibits the use of recycled wastewater for crop irrigation within 100 feet of an active domestic water supply well and the spray irrigation within 100 feet of a residence, school or public place to prevent public exposure to the recycled wastewater.

### 1.4 Facility Description

The STPUD facility permitted under the current RWQCB Order consists of a secondary wastewater treatment plant followed by filtration and disinfection, a 58 million-gallon emergency retention basin, an approximately 25-mile wastewater effluent delivery system, the man-made recycled wastewater reservoir and conveyance system. Raw wastewater is treated through a series of processes consisting of screening, grit removal, primary clarification, activated sludge treatment, secondary clarification, mixed media filtration and chlorination. The wastewater treatment plant has a dry-weather design capacity of 7.7 million gallons per day (mgd) based on annual peak-day flow.

Wastewater effluent from the treatment plant is pumped over Luther Pass through a force main and then flows by gravity to Harvey Place Reservoir in Alpine County. This export system is required to comply with applicable sections of the California Water Code that require the transport of all waste including wastewater effluent within the Lake Tahoe Basin to be transported out of the watershed.

The only authorized wastewater disposal areas within Alpine County for the STPUD wastewater effluent are Harvey Place Reservoir, Diamond Ditch, Fredericksburg Ditches and the irrigated land under a separate recycled water use regulations. As set forth in the 2004

RWQCB Order, STPUD is responsible for compliance with the monitoring and reporting program of the WDR.

#### 1.5 Monitoring and Reporting Requirements

The Monitoring and Reporting Program (MRP) of the RWQCB Order consists of nine areas of monitoring and analysis, of which only three are pertinent to the recycled wastewater application in Alpine County: surface water, groundwater, and soil monitoring.

The Alpine County groundwater monitoring program of the MRP stipulates that groundwater samples be collected monthly from 16 wells consisting of seven private water supply wells and eight groundwater monitoring wells. Samples of groundwater are to be collected from the upper three feet of the first groundwater encountered in each well and analyzed for the parameters listed in the MRP. The results of the monitoring and sampling program are required to be submitted to the RWQCB on a quarterly basis with an annual report submitted by June 15 of each year.

## 2.0 ENVIRONMENTAL SETTING

The environmental characteristics of the project study area pertinent to land application of recycled wastewater and evaluation of the effectiveness of the existing groundwater monitoring program are described in this section.

### 2.1 <u>Climate</u>

Alpine County, encompassing approximately 740 square miles in area, has a wide range of microclimates. The county extends from the central crest of the Sierra Nevada Mountains eastward to the eastern slope of the Sierra Nevada. The eastern slope part of the county can be considered as within the rain shadow of the west-facing slopes and generally receives less annual precipitation. Typically the majority of the county's annual precipitation comes in the winter months as snowfall. Due to the overall remoteness of the county there are relatively few precipitation gauges within the study area. Data compiled by others at the Woodfords/Markleeville station indicate the highest annual precipitation occurs in the months of December, January and February. Review of climate data for the Woodfords/ Markleeville station between 1948 and 2005 indicates the average highest precipitation that has historically occurred is approximately 93 inches. The highest average daily temperature of approximately 84°F occurs in July and the average lowest temperature of 16.9°F occurs in December.

#### 2.2 <u>Regional Hydrogeology</u>

Alpine County is located within portions of the Carson River, American River, Mokelumne River, Stanislaus River, and Truckee River watersheds. The majority of Alpine County is on the eastern slope of the Sierra Nevada and drains into the Carson River watershed. The four remaining watersheds contribute little or no recharge to the Carson River or Carson River watershed.

The Carson River watershed encompasses an area of approximately 4,000 square miles on the eastern slope of the Sierra Nevada in both California and Nevada. Approximately 50 percent of the Carson River watershed is located within Alpine County, including the southern portion of the Carson Valley and the headwaters for the Carson River.

The hydrology of Carson Valley is dominated by flow of the Carson River. The East and West Forks of the Carson River enter from the southern parts of the valley and flow northward to join near Genoa, Nevada. After the confluence, Carson River flows northerly and out of the Carson Valley southeast of Carson City, Nevada. Surface water from the Carson River is diverted across the valley floor through a network of canals and ditches for flood irrigation of crops and native pasture grasses. Thirteen perennial streams drain the Carson Range, whereas only two perennial streams, the Buckeye and Pine Nut Creeks, drain the Pine Nut Mountains Valley. The principal source of groundwater in the Carson Valley is the basin-fill deposits. Unconsolidated deposits beneath the basin, which range from clay to boulders, are present in thickness of up to 5,000 feet. The California Division of Mines and Geology map, Walker Lake Sheet, indicates the presence of alluvium in the northwestern and Diamond Valley portions of the basin. The southeastern portion and the southern apex of the basin are primarily Pliocene volcanics and Pleistocene non-marine. Most water supply wells drilled in the basin are completed in the basin-fill deposits (DWR unpublished data).

#### 2.3 <u>Project Site Geology and Hydrogeology</u>

The project study area is located in the Sierra Nevada geomorphic province between the Basin and Range province to the east and the Central Valley geomorphic province to the west. More specifically, it lies at the southern end of the Carson Valley groundwater basin and adjacent to the Carson Range in Alpine County.

Carson Valley is at the eastern base of the Sierra Nevada and straddles the California-Nevada state line in northern Alpine County. The California portion of the basin is about 10,700 acres. The West Fork of the Carson River flows northerly through the Carson Valley basin and is the confluence of many streams draining the eastern slopes of the Sierra Nevada. Scott Creek and Indian Creek flow through Diamond Valley, which is in the southern portion of the basin.

The floor of the valley is oval-shaped, approximately 20 miles long and 8 miles wide, and slopes from about 5,000 feet above mean sea level at the southern end to about 4,600 feet at the northern end. The Carson Range on the western side of the Sierra Nevada rises abruptly from the valley floor with mountain peaks ranging from 9,000 to 11,000 feet. The Pine Nut Mountains on the eastern side rise more gradually to peaks ranging from 8,000 to 9,000 feet.

The consolidated granitic and metamorphic bedrock surrounding and underlying Carson Valley are relatively impermeable to groundwater flow, although some wells produce sufficient water from fractures for domestic use. In the semi-consolidated Tertiary sediments, lenses of sand and gravel are the primary water-bearing units, and probably transmit most groundwater through the unit. Unconsolidated sediments that form alluvial fans surrounding the valley and underlie the flood plain of the Carson River are the principal aquifers within Carson Valley.

During a previous hydrogeologic reconnaissance conducted by STPUD, soil borings were drilled to depths of up to 770 feet in Diamond Valley. Volcanic rock (andesite) was encountered as shallow as 45 feet below ground surface (bgs) and as deep as 405 feet bgs and 770 feet bgs. The andesite encountered in these borings was interpreted as defining the bottom of the potentially water-bearing sand, gravels and other basin fill deposits in the study area.

#### 2.4 <u>Surface Water Features</u>

The primary surface water features within the project study area include the West Fork of Carson River and Indian Creek. The infiltration of surface water through streambeds and ditches and percolation of recycled wastewater from the flood-irrigated fields have

maintained the shallow water table beneath much of the valley floor where depth to ground water is less than 5 feet. Groundwater level beneath alluvial fans on the western side of the valley quickly increases to greater than 200 feet within one mile of the valley floor, whereas depth to water on the eastern side of the valley reaches 200 feet approximately three miles from the valley floor.

## 3.0 GROUNDWATER LEVEL MONITORING

The results of the groundwater level monitoring events performed for this evaluation study are presented in this section, including a description of the field procedures used for water level measurement.

## 3.1 Existing Groundwater Monitoring Network

The Monitoring and Reporting Program (MRP) included in Order No. R6T-2004-0010 for the Alpine County Groundwater Monitoring Program (Section V) listed the following monitoring points within the wastewater application area, the locations of which are shown on Figure 2:

| • | Domestic Water Supply Wells:  | GW-03, GW-04, GW-05, GW-07, GW-08, GW-11, and GW-14.                                                   |
|---|-------------------------------|--------------------------------------------------------------------------------------------------------|
| • | Groundwater Monitoring Wells: | ACMW-01AW, ACMW-01BE, ACMW-02N, ACMW-02S, ACMW-03W (former ACMW-03), ACMW-04W, ACMW-06N, and ACMW-06S. |

As required by the MRP, the STPUD monitors and samples these wells on a monthly basis for analysis of the required parameters. The results of the groundwater sampling and analysis are submitted in a quarterly report along with the results of the other MRP requirements.

As part of the hydrogeologic reconnaissance in 2003, three soil borings were drilled within Diamond Valley and converted into three dual completion groundwater monitoring wells. These wells (ACMW-07D, ACMW-07S, ACMW-08D, ACMW-08S, ACMW-09S, ACMW-09D) as shown on Figure 2, are currently not included in the Alpine County groundwater monitoring program of the MRP. Although STPUD monitors and samples these wells on a periodic basis, the results are not included in the monitoring reports submitted by the STPUD to the RWQCB for the groundwater monitoring program.

### 3.2 Site Reconnaissance and Well Inspection

On June 4, 2008, STPUD personnel accompanied Alisto to conduct a field reconnaissance of the permitted application areas and Diamond Valley, and a visual inspection of existing monitoring wells. The visual survey was performed to identify and evaluate potential locations for additional groundwater monitoring wells and assess the physical conditions of the existing monitoring wells.

Although the majority of the land application areas are relatively flat, the boggy ground conditions and surface water courses traversing the area could limit accessibility for drilling and monitoring of additional wells. Most of the potential well sites identified within the Alpine County wastewater discharge area can be accessed by buggy-mounted drilling equipment. Similarly, potential locations for additional wells were also identified based on year round accessibility using four-wheel drive vehicles. Other factors considered included:

access for drilling equipment, optimization of the existing well network; proximity to land application areas, surface water features and private water supply wells; and potential for snow burial of the wells during winter months.

All the existing monitoring wells were visually inspected as to their location relative to the monitoring network and application areas, physical condition and construction, and adequacy for collection of representative groundwater quality data. The visual inspection was performed to determine which of the existing wells will need to be abandoned and removed from the network, repaired and modified, or replaced to meet the objectives of Alpine County for monitoring the impact of wastewater application on groundwater, surface water and soil within the project area.

### 3.3 Well Surveying

All the monitoring wells at the wastewater application areas and at the emergency discharge area at Diamond Valley and selected domestic/private wells were surveyed on October 22 and December 11, 2007 by a California licensed surveyor in reference to the two survey control points (STPUD1 and STPUD2) established by STPUD for the Diamond Valley wells. The survey was performed to verify and establish the horizontal and vertical controls of each monitoring point to a common datum for use in interpreting the groundwater flow condition within the project area. The locations of the STPUD control points are shown in Figure 2, and a copy of the well survey data is included in Appendix A.

The wellhead survey of all existing monitoring wells was performed by Morrow Surveying of West Sacramento, California using global positioning system (GPS) equipment in reference to the two STPUD control points. The basis of the horizontal controls survey was the California State Plane Zone 2 and California Spatial Reference Center Datum, reference Epoch 2000.35. Continuously Operating Reference Stations (CORS) CH01 and CMOB were also incorporated in the GPS survey. The reference datum for the vertical control or elevation of each wellhead for the survey was the North American Vertical Datum (NAVD) 1988.

### 3.4 <u>Water Level Monitoring Procedures</u>

Groundwater level in all the existing monitoring wells within the wastewater discharge areas and the Diamond Valley emergency discharge area was measured from the permanent survey reference point at the top of the well casing during the four quarterly events. Alisto conducted the four monitoring events on September 24 and December 12, 2007; and on March 19 and June 4, 2008. STPUD personnel accompanied Alisto during all four events to provide access to the wells.

The depth to groundwater in each well was measured to an accuracy of 0.01 foot from the top of the PVC well casing using an electronic sounder. The field forms presenting the depth to water measurements during each event are included in Appendix B.

## 4.0 MONITORING DATA AND PROGRAM EVALUATION

An evaluation of the current groundwater monitoring program, data collected during the four monitoring events performed as part of this study, and available historical data provided by STPUD is presented in this section.

## 4.1 <u>Water Level Monitoring Results</u>

Depth to water data collected during the four monitoring events performed by Alisto in 2007 and 2008 are summarized in Table 1 including available historical data collected and provided by STPUD. The groundwater elevation at each well was calculated using the surveyed elevation of the top of well casing and the depth to water measured during each monitoring event. The surveyed location (longtitude and latitude) of each well together with the calculated groundwater elevation for each monitoring event were then used in interpreting groundwater flow direction and gradient and in preparing potentiometric groundwater elevation contour map for each monitoring event.

#### 4.2 Interpretation of Groundwater Monitoring Data

The interpreted groundwater flow direction and potentiometric contour maps for the monitoring events performed by Alisto in September and December 2007 and in March and June 2008 are shown on Figures 3 through 10. As interpreted from the results of the four monitoring events, the groundwater flow direction within Wade Valley and Carson Valley was consistently towards the north, generally following the flow direction of the Carson River. The interpreted groundwater gradient and flow direction within Diamond Valley was also consistently towards the north-northeast for all four events.

To determine if the shallow groundwater in the project area occurs in one hydrogeologic unit or if the water-bearing zone in Diamond Valley area is a discrete hydrologic unit from the Wade Valley and south Carson Valley area, two versions of data interpretations of the groundwater monitoring data were prepared for each quarterly monitoring event performed by Alisto. The two versions of groundwater flow and gradient interpretations were as follows:

- Version 1:Potentiometric groundwater elevation contour and gradient was interpreted<br/>using the groundwater level data from all the wells in Diamond Valley,<br/>Wade Valley, and Carson Valley as one hydrologic unit as shown on Figures<br/>3, 5, 7 and 9 for September, December, March and June events, respectively.
- **Version 2:** Potentiometric contour map and gradient was interpreted using water level data from the Diamond Valley wells separately from the Wade Valley and Carson Valley wells assuming each is a discrete hydrologic unit as shown on Figures 4, 6, 8, and 10 for the September and December 2007 and March and June 2008 events.

The groundwater contour maps and gradients based on the two versions of data interpretations indicate that the water bearing zones in Diamond Valley, Wade Valley, and south Carson Valley are hydraulically connected and do not appear to be two discrete hydrologic units. The interpreted groundwater flow direction and gradient for the four quarterly monitoring events are relatively consistent across the project area using both versions of data interpretation.

The difference in groundwater elevations between the farthest northerly monitoring point (ACMW-04) in Diamond Valley and the southernmost monitoring point (ACMW-07) is approximately 500 feet, which is consistent with the overall ground surface elevation change between the two monitoring points (approximately 650 feet). The changes in groundwater elevation over time in the monitoring wells as graphically shown on Figures 11 and 12 also reflect similar flow characteristics within the project area, indicating that the volcanic and volcaniclastic blocks between Diamond Valley and Wade Valley are not acting as hydraulic barriers to groundwater flow from south to north.

Based on the location and limited number of groundwater monitoring wells in the Carson Valley area, the groundwater flow and gradient direction cannot be adequately and reliably interpreted. However, the groundwater elevation in the northernmost well (ACMW-04W) was consistently lower than the other wells for all four quarterly events indicating the groundwater gradient is likely in a northerly direction.

Available geologic and hydrogeologic information on the project area was considered in developing a conceptual groundwater model to assist the preparation of potentiometric groundwater contour maps. It was assumed that the regional groundwater flow is through the alluvium generally from the higher elevations at the recharge areas along the basin margins towards the lower elevations within Diamond Valley and the wastewater discharge areas in Wade Valley and Carson Valley. Within the valley floor, groundwater flow is also influenced by pasture crop irrigation using recycled wastewater and surface water flow in the West Fork of Carson River and Indian Creek.

The gradient of the shallow groundwater in Diamond Valley is generally towards the northnortheast as shown on the potentiometric groundwater contour maps on Figures 3 through 10 for both versions of data interpretation. The slight difference in the interpreted gradient and flow direction between the two versions is due in part to the limited number and location of wells in the current monitoring network to reliably calculate and interpret groundwater flow conditions within the project area. Because of this limitation in the current monitoring network, it is likely that the groundwater quality data collected for this area is also not sufficient to properly evaluate the impact of the present and future discharges of recycled wastewater on groundwater quality within the project area.

#### 4.3 Groundwater Level Trend

Historical and recent groundwater level data collected over time are graphically shown on Figures 11 and 12. Although there is a data gap from 2004 to 2006, the shallow groundwater level in the Diamond Valley area shows an increasing trend from September 2007 to June 2008.

The groundwater level in the Wade Valley and Carson Valley has remained relatively consistent over time since 2005, most likely due to the influence of recycled wastewater application. The slight difference in water level trends between ACMW-06S, ACMW-06N, and ACMW-04W may be due to different methods of application, proximity to ditches and local evapotranspiration rates. Groundwater level in the project area, which is largely influenced by recharge along the basin fringes and stream flow, fluctuates seasonally and has generally been increasing since 2007.

#### 4.4 Evaluation of Current Groundwater Monitoring Network

From review and evaluation of geologic information and groundwater monitoring data, and visual reconnaissance of the monitoring network, it is evident that the number and location of monitoring wells are not sufficient to effectively and reliably interpret groundwater flow conditions within the present application areas of recycled wastewater and the Diamond Valley area. As can be noted in Figures 3 through 10, the number and location of wells of the current monitoring network does not adequately encompass the wastewater discharge areas to assess groundwater conditions in Carson Valley particularly at the eastern, western, and northern portions of the project area.

Evaluation of available geologic information and monitoring data collected during the recent quarterly events in 2007 and 2008 indicates that the regional flow direction of the shallow groundwater is generally towards the north-northeast in the Diamond Valley area and primarily to the north within Wade Valley and Carson Valley. These data interpretations are consistent with the results of previous monitoring events and the Diamond Valley hydrogeologic reconnaissance study conducted by STPUD.

Based on the two versions of monitoring data interpretation, it is apparent that the shallow water bearing unit beneath Diamond Valley, Wade Valley, and Carson Valley is hydraulically connected as one hydrogeologic unit. The volcanic and volcaniclastic blocks between Diamond Valley and Wade Valley are not acting as hydraulic barriers to groundwater flow from the south (Diamond Valley) towards Carson Valley and the California-Nevada border. The hydrogeologic characteristics of the project area should be considered in developing a comprehensive and effective groundwater monitoring program to reliably address and assess the impact of present and future wastewater discharges on groundwater quality within the land application areas and to properly protect water supply sources in the region.

## 5.0 RECOMMENDATIONS

Based on the results of the water level monitoring and evaluation of available data, following are the recommendations to the existing groundwater monitoring network and program of STPUD for the recycled wastewater discharge within Alpine County.

- Modify, repair, or destroy selected wells included in the current monitoring network to improve data reliability and wellhead protection and security.
- Install additional monitoring wells at the present and future wastewater discharge areas in two phases in accordance with applicable regulatory standards and Alpine County Groundwater Management Plan.
- Evaluate and determine the appropriate water quality parameters for use as indicators of impact of wastewater discharge on groundwater quality.
- Conduct an on-going evaluation of the effectiveness and adequacy of the monitoring program and network to determine the need for modifications to address future changes in regulations and land application areas and practices.

Detailed discussion of each of the above recommendations is presented below and the recommended modifications to the existing monitoring network are presented in Tables 2 to 4. The proposed locations of the additional monitoring wells are shown on Figure 13 and described in Tables 3 and 4.

### 5.1 <u>Recommended Modifications to Existing Monitoring Wells</u>

The construction and current condition of each well included in the current monitoring program are described in Table 2 including the well-specific recommended action or modification based on field observations, applicable requirements of RWQCB Order No. R6T-2004-0010, and regulatory guidelines. The recommended modifications or actions for the existing wells include the following:

- Replacement of selected wells listed in Table 2 with properly constructed wells to ensure collection of reliable data that are representative of site conditions
- Modification of wellhead construction as listed in Table 2 for improved protection, security, and accessibility.
- Destruction of wells that are no longer included in the monitoring network or considered to be deficient for use in monitoring.

The recommended actions for the existing wells as presented in Table 2 were developed in conjunction with the proposed modifications to the monitoring network and program described in the following sections.

#### 5.2 <u>Recommended Modifications to Current Monitoring Well Network</u>

As discussed in the preceding section, the current groundwater monitoring network is limited and not adequate for collection of representative data to effectively and reliably assess groundwater conditions and the impact of recycled wastewater discharge on groundwater quality beneath the present and future application or discharge areas. In determining the number and potential location of additional wells, the following criteria were used:

- Applicability and adequacy to evaluate the geologic and hydrogeologic conditions and impact on groundwater quality.
- Accessibility for drilling and well installation and year-round monitoring and sampling.
- Right-of-way access or likelihood of obtaining access permit from property owner.
- Optimization of existing well network and proximity to land application areas, surface water features and private water supply wells.
- Location of other potential sources of contaminants to groundwater.
- Compliance with Federal, State, and local regulatory requirements and specific provisions and intent of the RWQCB Order for discharge of recycled wastewater.
- Consistency with the objectives of this evaluation study and with the Alpine County Groundwater Management Plan.

During field reconnaissance in June 2008, a total of 11 potential additional well sites were identified by Alisto and STPUD personnel. Subsequently, STPUD personnel identified eight additional potential well sites. Based on field observations, requirements of RWQCB Order No. R6T-2004-0010, and review of available historical data, it is recommended that installation of additional wells be implemented in two phases. The potential locations of proposed additional wells for Phase 1 are listed in Table 3 and in Table 4 for Phase 2. Each phase of the implementation plan for the recommended modifications to the current monitoring network is described below:

- **Phase 1:** Installation of additional monitoring wells at 10 locations within the active land application areas in Carson Valley and Wade Valley to address the limitations in collecting representative data that is adequate and effective in evaluating hydrogeologic conditions and impact on groundwater quality.
- **Phase 2**: Installation of additional wells at 7 locations within the emergency discharge area in Diamond Valley before conversion and use as a permanent discharge or application area to obtain sufficient water level and quality data in the future. These additional wells are also necessary to collect sufficient baseline data on water quality within Diamond Valley to comply with future regulatory requirements.

Of the total 17 additional monitoring points proposed for the two phases, monitoring wells at the 10 locations under Phase 1 are recommended to be installed as soon as practicable after receipt of concurrence of regulatory agencies and STPUD. The additional wells under Phase 2 are recommended to be installed before converting and using the Diamond Valley area as a

permanent recycled wastewater application or discharge area in order to collect sufficient baseline groundwater level and quality data to comply with regulatory requirements.

As stated in the preceding section, the current monitoring well network and configuration within the active wastewater application areas is limited and not adequate to collect data to reliable interpret groundwater flow conditions. As such, it is also apparent that the current monitoring network is likely not adequate to collect data that is representative of site conditions to assess the impact of wastewater discharge on groundwater quality in south Carson Valley and Wade Valley at this time. The number and location of the proposed additional wells were therefore selected to address the potential data gaps in groundwater flow conditions and quality.

The purpose and rationale for each additional well proposed under Phase 1 are described in Table 3 and summarized below:

- <u>Wells A-1, A-6, and A-8:</u> Monitoring of groundwater elevation and water quality indicator parameters in the shallow groundwater as sentinel wells to assess potential impact of wastewater discharge and migration of constituents of concern (COC) in recycled wastewater on groundwater downgradient of the discharge areas and upgradient of the California-Nevada border.
- <u>Wells A-4, A-5, and A-9</u>: Monitoring of groundwater elevation and water quality parameters to assess impact within the application areas.
- <u>Well A-7</u>: Monitoring of groundwater elevation and shallow water quality along the western margin of the application and recharge areas.
- <u>Well A-2</u>: One well to monitor the shallow groundwater elevation and water quality at the eastern margin of the application area and as a recharge monitoring point for application ditches in T11N, R20 E; Section 17. One deep well next to the shallow well to serve as a sentry monitoring point to assess potential impact of the active sewage treatment ponds in NE ¼ of SW ¼ of Section 21 on water quality.
- <u>Wells A-3 and A-10</u>: Monitoring of shallow groundwater elevation and water quality at the southern margin of the application areas. A-10 would serve as monitoring point for Diamond ditch to the south and Well A-3 would monitor the active land application area in Wade Valley upgradient of the pivot irrigation system.

Table 4 lists the additional wells proposed under Phase 2 including the rationale and proposed construction. The unidentified well in Diamond Valley, north of Well ACMW-02 should be further investigated to determine its construction and use for possible inclusion into the monitoring program. If the construction of this well does not meet regulatory standards and is not suitable for use as a monitoring well, it is recommended that this unidentified well be properly destroyed. Proposed Wells B-5 and B-6 under Phase 2 will adequately monitor the groundwater elevations and water quality at the northerly edge of the Diamond Valley emergency discharge area.

If the pH and chloride level in existing well ACMW-07 have been consistently elevated as compared to the other wells, it is recommended that this well be properly destroyed. As

described in the boring log and construction details, Well ACMW-07 was grouted up to a depth of 163 feet and then re-drilled to its current depth of the well at 345 feet. Drilling fluids and neat cement have likely penetrated the sidewalls of the boring and adversely affected groundwater quality resulting in higher chloride level.

#### 5.3 <u>Recommended Specifications and Procedures for Monitoring Well Construction</u>

Due to the variability of subsurface soil and rock in the project area, it is recommended that the additional wells be installed with a drilling rig equipped with a casing advance system (such as Odex/Stratex or equivalent). Casing advance drilling method ensures the boreholes will remain open during advancement and well construction and eliminates the generation of waste stream of a mud rotary drilling method. Undisturbed and uncontaminated soil samples can be collected ahead of the working face of the boring with a split spoon sampler using this method. In addition, casing advance methods are preferred due to its ability to advance through boulders and rocks as well as fine sediments without the introduction of drilling fluids into the water bearing sediments. Since no drilling fluid is used, the drill cuttings are typically discharged to the ground surface as compared to the drill cuttings generated by mud drilling method that requires transportation to an offsite disposal facility.

At locations where a combination deep and shallow monitoring well is recommended, multiple completion or nested wells are not recommended because of the potential for vertical communication between the screened intervals within the same borehole. In installing a dual shallow and deep monitoring point, the shallow well should first be drilled, logged and constructed to the appropriate or targeted water-bearing zone. The boring for the deep well should be drilled a minimum of 10 feet away without logging or sampling the interval from ground surface to the depth of the shallow well. The boring for the deep well should be logged and sampled beginning at the bottom depth of the shallow well to the proposed total depth of the deeper well. Soil samples should be logged in the field by a qualified geologist or engineer in accordance with the Unified Soils Classification System.

The construction of a groundwater monitoring well should be in accordance with the Alpine County Groundwater Management Plan with respect to construction materials, filter pack, sanitary seal and wellhead completion. A sample construction diagram of a groundwater monitoring well is shown on Figure 14.

A groundwater monitoring well is typically constructed of blank Schedule 40 polyvinyl chloride (Sch. 40 PVC) casing from the surface to approximately 5 feet above the groundwater level encountered during drilling to allow for seasonal water level fluctuation. The screened interval of the shallow well should extend a minimum of 10 to 15 feet below the top of the encountered groundwater level using factory slotted Sch. 40 PVC casing. For deep wells extending to depths of 50 feet or deeper, well centralizers should be used at interval of 25 feet.

After the casings have been placed in the boring, an appropriate filter pack is placed around the well screen interval to a depth of approximately 5 feet above the screen. A sand pack is then placed inside the drive casing using the tremie method to reduce bridging. As the filter pack is emplaced, the drive casing is removed a section at a time to ensure the drive casing is not above the top of the sand pack. The screen interval should be swabbed to eliminate bridging of the sand filter pack, optimize well production, and minimize intrusion of fines into the well. After swabbing, the depth to the top of the filter pack is tagged and if the filter pack has settled, additional sand should be added. Once the filter pack has been installed, a 2- to 3-foot thick bentonite spacer is placed above the sand pack, and the remainder of the boring annulus is sealed with Portland Type I/II neat cement using the tremie method.

All well surface completions should consist of a lockable stovepipe monument set in a minimum 3 feet by 3-feet by 6-inch thick concrete pad. Where practicable a minimum of three bollards should be installed around each wellpad to protect the monument from damage by snow removal equipment, livestock, and/or vehicle.

After a minimum of 48 hours after installation of the sanitary seal, each well should be developed by removing at least 10 saturated borehole volumes from the well as measured from static water level to the well's total depth. Development should be performed with either a variable speed submersible pump, airlift pump or bailer. During well development, indicator parameters pH, temperature, specific conductivity and turbidity should be measured using a calibrated field instrument. Development purging should continue until the indicator parameters have stabilized and vary by no more than the following values:

- pH 0.2 units
- Temperature 0.5 degrees Celsius
- Specific conductivity 10 percent
- Turbidity 20 ntu

After stabilization of the above indicator parameters, a sample of groundwater should be collected from the well using a clean disposable Teflon bailer and placed in appropriate laboratory-supplied containers for analysis of COC. Samples collected must be transported to a certified laboratory following standard chain-of-custody procedures.

Actual site conditions such as first encountered groundwater and characteristics of sediments encountered during drilling of the boring will determine the specific well construction based on observation in the field by a qualified geologist or engineer. After development and collection of initial groundwater sample from the well, each well can be equipped with a dedicated pneumatic airlift pump or bailer to eliminate potential for cross contamination during future sampling events.

## 5.4 Evaluation of Water Quality Indicator Parameters

The scope of work for this monitoring program evaluation study does not include an assessment of the groundwater quality parameters or constituents of concern being analyzed in the groundwater under the current RWQCB Order. It is recommended, however, that Alpine County and STPUD re-evaluate the current groundwater sampling and analysis plan to determine if the current COC and monitoring parameters being analyzed are appropriate indicators of wastewater discharge impact on groundwater quality. The re-evaluation of

monitoring parameters should also consider constituents that are specific indicators of other potential sources of contaminants to groundwater other than wastewater discharges from STPUD.

The selection of the appropriate chemical and/or biological indicator parameters should be one of the primary objectives in evaluating the current water quality sampling and analysis requirements of the RWQCB Order for the STPUD wastewater discharge program in Alpine County. At this time, the constituents of concern outlined in the MRP of the RWQCB Order appear to be adequate to assess the potential impact of recycled wastewater discharge on groundwater quality. Groundwater samples are required to be collected by the discharger on a monthly basis as outlined in Section V; Page 6 of the MRP.

After installation of the proposed additional monitoring wells and collection of sufficient data set (at least one year of data), it is recommended that Alpine County and STPUD re-evaluate the sampling and analysis plan to determine the adequacy and applicability of the monitoring parameters in assessing the impact wastewater discharge on groundwater quality. Revisions or modifications to the list of monitoring and indicator parameters that are deemed warranted should be submitted to the RWQCB for consideration and approval before implementation.

### 5.5 Ongoing Evaluation of the Groundwater Monitoring Program

Because of future changes in regulatory requirements, wastewater treatment technology and discharge practices, agricultural irrigation practices, and environmental conditions within the project area, Alpine County and STPUD should evaluate the effectiveness and adequacy of the groundwater monitoring program on an ongoing basis. This ongoing evaluation should also focus on the adequacy of the sampling and analysis plan in collecting representative data on the indicator parameters of impact on groundwater quality.

NOTES:

Not currently included in the groundwater monitoring network as set forth in the Monitoring and Reporting Requirements of Order No. R6T-2004-0010

[A] Verify if chloride or TDS levelis elevated compared to other Diamond Valley wells; well was installed in a re-drilled boring that was previously grouted up.

UNK Unknown, data or information on well not available

South Tahoe Public Utility District Recycled Water Facilities Master Plan

## Appendix I-b - Farr West Report - Phase 1 Irrigation Fields Monitoring Well Installations, Diamond Valley, Alpine County, CA

April 3, 2009

Mr. Ivo Bergsohn, P.G., C.Hg. Hydro-Geologist South Tahoe Public Utility District 1275 Meadow Crest Drive South Lake Tahoe, California 96150 IBergsohn@stpud.dst.ca.us

Subject: Phase 1 Irrigation Fields Monitoring Well Installations, Diamond Valley, Alpine County, California (FWE Project: STPUD 08-01)

Dear Mr. Bergsohn,

This letter report documents soil sampling, well construction and water quality sampling conducted for the South Tahoe Public Utility District (District). The purpose of the project was to determine the depth and thickness of water-bearing zones, construct monitoring wells and collect baseline water quality data. A brief chronological executive summary is provided below with an in depth discussion provided in the body of this letter report with figures, tables, permits, analysis, etc. provided as attachments.

### EXECUTIVE SUMMARY

- 1. Soil sampling, well construction and water quality sampling were conducted in northern Diamond Valley, Alpine County, California. The work was completed in accordance with the objectives of the September 29, 2008 Workplan which was prepared by Ivo Bergsohn, the District's Hydro-Geologist, and approved by the Regional Water Quality Control Board-Lahonton Region (RWQCB-LR). Farr West Engineering, Reno, Nevada, provided hydrogeologic supervision and subcontracting for field and laboratory work performed. Permits for boring and well construction were obtained from the Alpine County Health Department. The boring sites were marked and a utility clearance request was received by USA North one week prior to the borings.
- 2. Boring activities were conducted on November 3rd and 4th, 2008 by Boart Longyear, Yuba City, California utilizing a truck mounted sonic drilling system with split spoon sampling capability. Soil samples were collected continuously from unconsolidated alluvial units from three sites with borehole depths between 32.5 to 72.5 feet below ground surface (bgs).

April 3, 2009 Page 2

- 3. The borings contained minor organic material between 1 and 2 feet bgs with interbedded silty sands to well graded sand with silt and impermeable units comprised of silty, clayey sands with minor gravel and rare cobbles up to approximately 8-inches in diameter. Direct push split spoon samples and samples oriented vertically and horizontally (collected directly from the sonic core) were submitted for laboratory geotechnical analysis. Soil classifications from the geotech analysis ranged from silty sand (sm) and silty, clayey sand with gravel (sc-sm) in borings ACMW-10 and ACMW-12 and well graded sand with silt (sw-sm) in boring ACMW-11. Hydraulic conductivities from laboratory analysis ranged from the lowest of 0.06 ft/day in well ACMW-10 to the highest of 1.58 ft/day in well ACMW-11.
- 4. The Boart Longyear crew conducted well construction activities on November 3, 4 and 5, 2008. Two wells (ACMW 10 and ACMW 11) were screened in the shallow alluvial water bearing zone. Well (ACMW 12) was screened below perched water encountered in the shallow alluvial zone in the underlying lower alluvial zone.
- Well development was conducted for the three wells on November 7, 13 and 14, 2008. Development was continued until water generated from the purge pump did not contain observable turbidity. Because of poor production during sampling, ACMW 10 was redeveloped on December 8, 2008.
- 6. Surveying of wellheads was conducted on November 11, 2008 and repeated on December 3, 2008 utilizing GPS methods by Morrow Surveying of West Sacramento, California. A stamped survey plot with the well coordinates was revised and finalized (December 16, 2008). Depth to water in the boreholes ranged from approximately 21.38 to 36.87 feet bgs and suggests that the shallow alluvial water bearing zone has a hydraulic gradient to the east.
- 7. Baseline groundwater sampling was completed for the three wells on November 19, 2008. Groundwater sampling was conducted after water quality parameters had stabilized. Samples were transported to Western Environmental Testing (WET), Sierra Environmental Monitoring (SEM) and the District lab for analytical analysis under chain of custody.
- 8. Protective measures were in place to prevent release of contaminants during project activities. No contaminant releases occurred associated with this project. Water generated and released during project activities infiltrated the ground surface and did not enter any irrigation ditches or drainages.

### BACKGROUND

On September 29, 2008 the South Tahoe Public Utility District (District) provided a Workplan for the installation of three monitoring wells to the Lahonton Regional Water Quality Control Board. The following background information is from the Workplan:

The District is designing irrigation fields that will serve a dual purpose. Their primary use will be as an irrigation site for land application of reclaimed wastewater. During emergencies, especially in response to a flood event, the fields will also provide an area for emergency discharge and temporary containment. After the emergency event is over, the contained water will be pumped back to Harvey Place Reservoir.

The design concept for the proposed irrigation fields allows flood and sprinkler irrigation, useable in all seasons. Initially the facility may be irrigated with existing freshwater rights diverted from the West Fork of the Carson River. As the potential need for recycled application area grows in response to potential development of existing application areas, reclaimed wastewater may be used to irrigate the Irrigation Fields.

The existing emergency reclaimed wastewater facility (a.k.a. "On-Farm") was evaluated and found to be insufficient for emergency discharge needs. Sites for new emergency facilities (the irrigation fields), have been identified in Fields 1, 2, 3, 6 and part of Field 7. Based on the topography and layout of Diamond Valley Ranch, the District has determined that Fields 6 and 7 are the most feasible candidates for emergency discharge and temporary containment in the first phase.

Two irrigation fields have been planned along the western perimeter of Field 6. The fields are designed to follow the natural contour of the surrounding area, sloping toward the northeast. The maximum cut of the irrigation fields is estimated at about 9 feet. Each field will be bounded by a 6-ft tall berm on its down-slope side. Because the berms are 6-ft tall, they are not governed by the California Division of Safety of Dams regulations.

The area of the planned irrigation fields will be initially used for a demonstration project to ascertain the potential effects of applying reclaimed wastewater to land in Diamond Valley. Information gained from the demonstration project will be incorporated into a Nutrient Management Plan for the area. To evaluate hydrogeologic conditions near the planned irrigation fields, prior to the application of reclaimed water, and to establish a groundwater monitoring system after the irrigation fields are put in service, the District plans to drill and install groundwater monitoring wells.

### HYDROGEOLOGIC INVESTIGATION

The northern area of Diamond Valley has been mapped as Quaternary moraine, younger outwash and valley-fill deposits (Armin and John, 1983) Borings drilled by the District prior to this Workplan encountered poorly-graded mixtures of medium to coarse granitic sands, gravels and boulders with rare thin layers of clayey sand and silt within the Quaternary deposits. Units underlying the Quaternary deposits include andesitic tuffs, lavas and alluvial materials encountered at depths varying from 40 feet to as much as 480 ft below ground surface. These underlying deposits have been mapped as Tertiary Volcanics (Armin and John, 1983).

The work was completed in accordance with the objectives of the September 29, 2008 Workplan, which was prepared by Ivo Bergsohn (STPUD District Hydro-Geologist) and approved by the Regional Water Quality Control Board-Lahonton Region (RWQCB-LR). Farr West Engineering, Reno, Nevada, provided hydrogeologic field supervision and subcontracted with the drilling, survey and laboratory contractors. Permits for boring and well construction were obtained from the Alpine County Health Department. The boring sites were marked and a utility clearance request was filed with USA North. The STPUD advised of buried electrical utilities in the vicinity of ACMW-10

Three sonic borings and associated monitoring wells were constructed at locations shown on the map presented in Figure 1 and photographs presented in Figure 2. An alternate well location to the west of the initial three proposed locations was selected and permitted prior to the start of the field project. This location was drilled and completed as a monitoring well (replacing the proposed IFMW-03p site) to help constrain the gradient of the shallow alluvial water bearing zone. Permits and utility clearance requests are included in the report as attachments. Locations and elevations were surveyed on November 11, 2008 and repeated on December 3, 2008 utilizing GPS methods. Morrow Surveying of West Sacramento, California provided final stamped survey drawing (dated December 16, 2008) and data tables for the survey (attached). A compilation of selected monitor well data from the projected is provided Table 1.

### Borings

Sonic drilling was conducted November 3 and 4, 2008 by Boart Longyear of Yuba City, California (C57#694686) utilizing a truck mounted rig. The sonic drilling method was selected as the most cost effective drilling method that could drill through boulders, if necessary. Sonic drilling also provided the benefit of economically collecting continuous samples from the unconsolidated alluvial units. Borings were drilled utilizing sonic methods or pushed with the split spoon sampler to maximum depths from 32.5 to 72.5 feet below ground surface (bgs). Daily drill reports, California Driller's reports and borehole logs are provided as attachments.

April 3, 2009 Page 5

In general the borings contained minor organic material in the upper most interval grading into interbedded units with low hydraulic conductivity comprised of silty sands, silt with minor gravel and rare cobbles up to approximately 8-inches in diameter. Some of the more consolidated units provided significant resistance for the truck mounted rig to sonically drill and push the split spoon sampler. Boulders were not encountered as had been anticipated in the glacial moraine deposits. Tertiary volcanic bedrock encountered in previous borings at relatively shallow depths (ACMW-09) were not encountered in any of the borings.

Borings ACMW-10 and ACMW-11 encountered materials of low to moderate hydraulic conductivity, respectively, and the materials remained saturated to total depth after encountering the water table. Because of a known perched water horizon in the northern portion of the proposed irrigation fields and the proximity of ACMW-12 to ACMW-09 the District Hydrogelogist requested drilling of ACMW-12 below the perched water. Perched water was encountered at a depth of between 32 and and 37 feet bgs. A confining layer comprised of silt with variable gravel was encountered from 37 feet bgs to 57 feet bgs. A water bearing zone was then encountered at depths from 57 feet bgs to the boreholes total depth of 73.5 feet bgs.

Brass sleeves pounded directly into the sonic core by hand and brass sleeves in a split spoon sampler hydraulically pushed by the drill rig were submitted for geotechnical analysis. In general, the samples extracted from the split spoon sampler had higher bulk density than the in-situ material because pushing the split spoon sampler required significant force and may have caused some compaction of the samples during the sampling event. Sampling with a conventional split spoon hammer would probably have resulted in refusal of the sampler for several of the samples because of the density and nature of the in-situ material. Samples extracted from the sonic core may have had lower bulk density than the in-situ material because granular material had an opportunity to expand as the core is released from the sonic core barrel. Bulk density is inversely related to the porosity of the soil. It is possible that changes in bulk density may have affected the hydraulic properties of the soil samples.

AMEC was selected for testing of soil samples because of reliable results during previous laboratory efforts for the District and to provide consistency from previous work performed for the District. Laboratory analysis of the soil samples confirmed the generally low hydraulic conductivities of the soil samples identified in the field and observed during development pumping of the wells. Unified Soils Classification System description from the laboratory analysis ranged from silty sand (sm) and silty, clayey sand with gravel (sc-sm) in borings ACMW-10 and ACMW-12 and well graded sand with silt (sw-sm) in boring ACMW-11. A summary of the geotechnical laboratory analysis is presented in Tables 2 and 3. Data sheets from the laboratory analysis are provided as attachments.

April 3, 2009 Page 6

Hydraulic conductivities from laboratory analysis ranged from 0.06 ft/day in ACMW-10 to 1.58 ft/day in ACMW-11. The comparison of hydraulic conductivity results from samples extracted horizontal to the core and samples extracted vertical to the core were similar. The vertical samples had hydraulic conductivities approximately 15% greater than the horizontal samples. The lower horizontal hydraulic conductivity could be because the samples were compromised because the 6-inch width of the core did not provide a sufficient length from which to extract the samples. Three separate cylinders from a sample depth of 61 feet in ACMW-12 were not tested for hydraulic conductivity because voids indicated that the sample had been disturbed.

Slight changes in grain size distributions between ACMW-11 23.0-23.5 and 25.5 H and 25.5-26.0 V demonstrates the effect that small changes (as low as two percent in the percentage of fines) can have on hydraulic conductivity which resulted in more than an order of magnitude difference. Hydraulic conductivities of the samples range from higher values, typical of fine to coarse sand, to lower values, typical of glacial till. These values are indicative of poor aquifer conditions and are orders of magnitude below what would be required for significant infiltration or municipal groundwater production. This hydraulic analysis supports earlier studies for the area indicating that the material in the northern Diamond Valley area is not suitable for aquifer storage and recovery (ASR).

### **Well Construction**

The Boart Longyear crew conducted well construction activities on November 3, 4 and 5, 2008. Two wells (ACMW 10 and ACMW 11) were completed with 20 foot screened intervals that intercept the water table. The third well (ACMW 12) was completed below the perched water into the underlying confined lower alluvial zone with a 20 ft screen interval. After completing ACMW-12 the water level rose above the elevation of screened interval which was positioned adjacent to the permeable material below the confining layer.

The specific depths of well screen, casing, filter pack and seals for the most part follow the Workplan (Figure 3) and are shown on Table 1. Dennis Lampson of Alpine County Health provided verbal permission to complete well ACMW-11 with a cement seal of 10 ft so that the screened interval could be positioned across the water table. Well construction activities followed the Workplan except for the use of schedule 40 PVC instead of schedule 80 PVC casing in well ACMW-12 because of screen availability.

April 3, 2009 Page 7

A protective steel locking well cover was installed to protect the wells prior to the contractor moving off the site. Alpine County Health did not require bollards to protect the wells because the wells are not adjacent to improved roads. Installation of bollards around the wells would provide additional protection to the wells during ranching or excavation for the temporary containment structures.

### **Protection of Environment**

Environmental protection in place during drilling and construction activities included plastic sheeting placed beneath drilling equipment and straw wattles were placed between equipment and irrigation ditches to intercept any accidental releases. The drilling method and dry weather conditions during the field program eliminated the potential for runoff from the work sites. Soil samples were collected in plastic bags and brass core tubes. All of the cores from sonic drilling have been located near site ACMW-10 adjacent to the weather station. Fluids generated during well development and water quality sampling infiltrated on site away from irrigation ditches. During boring, well construction, well development and water quality sampling no materials or fluids entered any surface watercourses.

### Well Development

Because of the sonic drilling method, surge block development was not deemed necessary and not implemented by the drilling contractor. Well development was conducted by over pumping the monitoring wells on November 7, 13 and 14, 2008. Development was continued until water generated from the purge pump did not contain significant turbidity. Because of poor production during the water quality sampling event, ACMW 10 was redeveloped on December 8, 2008. Development with the purge pump utilized as a pump and surge block was adequate at agitating the well and breaking fine materials away from the well bore. Because of the use of schedule 80 casing, a standard 2-inch MonoFlex surge block will not fit in ACMW-10 and ACMW-11.

### Water Quality Sampling

Farr West Engineering contracted with Western Environmental Testing (WET), and Sierra Environmental Monitoring (SEM) for analytical analysis. Western Environmental Testing (WET) was selected because of their ability and experience achieving the detection limits and methods requested by the District. Terry Powers, the District's Laboratory Manager, allowed WET to use alternate analytical methods from that of the Workplan. The alternate methods will meet regulatory compliance requirements according to the District. A limited selection of laboratories perform the prescribed method for coliform analysis and SEM was selected for the analysis because of their familiarity with the methods and previous work with the District.

<sup>5442</sup> Longley Lane, Suite B • Reno NV 89511 • (775) 851-4788 • FAX (775) 851-0766

April 3, 2009 Page 8

Baseline groundwater sampling was completed for the three wells on November 19, 2008. Groundwater sampling was conducted after water quality parameters had stabilized during purging of the wells. Samples were transported to WET, SEM and the STPUD laboratory for analytical analysis under chain of custody. Table 4 provides a summary of the analytical results. Analytical data sheets are provided as attachments.

Fecal and total coliform were analyzed below detection limits. The absence of coliform is understandable because of the semi pervious character of layers between the surface and water table. Even though all equipment was washed and rinsed as prescribed in the Workplan during the processes of drilling, well construction, well development and sampling coliform can be introduced to the well during well construction, which can increase with time. Neither well construction materials or the well has been chlorinated and positive coliform counts could develop and increase with time if conditions are favorable to coliform growth.

The laboratory results present bicarbonate alkalinity in mg/L and total alkalinity in mg/L CaCo3. These different units are based on historically accepted regulations/requirements. If the values for bicarbonate are converted to mg/L CaCO3 the values for bicarbonate and total alkalinity are nearly identical as should be the case since the carbonate and hydroxide components are below detection limits.

The total dissolved solids (TDS) value from sample ACMW-10 appears high compared to the EC. The lab reanalyzed the EC and obtained the same value, which is in agreement with the value obtained with the field meter at the time of sampling. The laboratory did not have an explanation for the anomalous results and was unable to rerun the sample because the sample had exceeded the hold time. Therefore the anomalous, higher than expected (based on EC) TDS value is probably incorrect. Laboratory error or suspended solids from inadequate development of the well are probably the cause of the anomalous TDS value.

The concentration of water quality parameters in the three wells correlates inversely with the groundwater yield of the three wells. This can be related to either inadequate development of the well and possible incorporation of suspended solids during sampling or that the more productive wells have higher transmissivity and thus the water encountered in the well could have shorter resonance time in the aquifer to acquire increased concentration of constituents.

April 3, 2009 Page 9

#### Water Bearing Zones

Water level data from existing monitoring wells, hydrogeologic data collected during drilling and water level data from the new monitoring wells constructed and surveyed during this project indicates that low to virtually impermeable material separates multiple permeable units. The informal discontinuous alluvial units are separated into two groups in this report and referred to as the shallow alluvial zone and lower alluvial zone. The shallow alluvial zone can be under the direct influence of surface water, locally includes perched water zones, and is generally less than 40 ft bgs. Alluvial units between the upper alluvial zone. Water levels in the shallow alluvial zone. The water levels in the shallow alluvial zone. The water levels in the shallow alluvial zone can be greater than the lower alluvial zone. The water levels in the shallow alluvial zone can be greater than ten feet higher in elevation than water levels in lower alluvial zone. In general, the water level elevation difference between shallow alluvial zone and lower alluvial zone is less than several feet. The extent of the downward gradient is poorly understood because of the lack of sites with multiple wells.

#### **Shallow Alluvial Zone**

Several factors make the creation of a potentiometric map of the shallow alluvial zone difficult. These factors include topographic relief of greater than 100 feet within less than 1/4 mile of the proposed irrigation fields, discharging springs and several ditches that provide sources of recharge. Even within the shallow alluvial zone, semi-confined conditions within individual alluvial units result in depth to water measurements not representing unconfined water table conditions. Because of these factors, several more wells would be required in the shallow alluvial zone to constrain the unconfined water table surface. Based on the limited wells, ACMW-10 and ACMW-11, completed in unconfined units within the shallow alluvial zone and observations during drilling at ACMW-12 the hydraulic gradient of the shallow alluvial zone in the area of the proposed irrigation fields is generally to the east. Seasonally groundwater from the shallow alluvial zone could discharge in the vicinity of Indian Creek. During the January 2009 sampling event the eastward gradient decreased significantly because the water levels in the north dropped which is attributed to decreases in the flow rate in Snowshoe Ditch #2 and increases in discharge rate in the ditch near ACMW-11.

Several water levels obtained in ACMW-09S are coincident with the bottom of the screen interval and may indicate that the well is not in good hydraulic communication with saturated materials. Thus developing a potentiometric surface without conformation that the well is in hydraulic communication may provide an inaccurate water table surface. Although ACMW-07S and ACMW-08S are screened below the water table, these wells provide minimum water surface elevations, which are coincident with the potentiometric surface that the other shallow wells are completed within.

April 3, 2009 Page 10

#### Lower Alluvial Zone

Wells ACMW-08D, ACMW-09N and ACMW-12 are screened in the lower alluvial zone and could all be down gradient of the proposed irrigation fields due to hydraulic mounding caused by infiltration and radial flow from the irrigation fields. There is a greater probability that the hydraulic gradient represented by these wells will continue to the east during most conditions. This theory is supported by the potential for recharge from the Snowshoe Ditch #2 to the northeast, the probability that the lateral moraine deposits to the northwest are less permeable and that the water levels in the lower alluvial zone are more similar to the Indian Creek (~5550 ft) than the Carson River (~5350 ft) discharge level indicating that the glacial moraine forms a significant hydraulic barrier. Local seeps and springs may discharge above the level of the Carson River. The direction of the hydraulic gradient of the lower alluvial zone below the water table is probably not as significant to the project because the water that infiltrates below the containment structure will flow predominantly in the down gradient direction of the shallow alluvial zone.

#### SUMMARY

The proposed irrigation and temporary containment area at Diamond Valley could receive reclaimed wastewater with low infiltration rates into the upper most portion of the shallow alluvial zone because of the generally fine-grained poorly sorted material. Movement of water from the shallow alluvial zone to the lower semiconfined and confined alluvial zones will be minimal because of the interbedded alluvial and morainal deposits that form confining layers that will retard infiltration.

Water level data collected from existing monitoring wells, water level data collected during drilling and data from the new monitoring wells (constructed and surveyed during the project) indicates that locally confining layers with virtually impermeable material (comprised of morainal deposits) to low hydraulic conductivities separate multiple aquifers. These confining layers have resulted in seasonal water levels in the unconfined zones being greater than ten feet higher in elevation than underlying semi-confined and confined water zones. Quantifying the vertical and horizontal groundwater gradients will require careful evaluation of well construction and seasonal water level data.

The horizontal and vertical hydraulic gradients are dynamic seasonally because of the combination of seasonal recharge from irrigation, low hydraulic conductivities, significant source of recharge (from groundwater and surface water) and topographic setting between two drainages that discharge groundwater seasonally. The change in hydraulic gradients can seasonally exceed an order of magnitude and could significantly change the direction of groundwater flow.

April 3, 2009 Page 11

This field project was successful in collecting data to characterize the hydrogeologic characteristics of the northern Diamond Valley area for temporary containment and irrigation. The sonic drill rig was the appropriate equipment for collecting the required data resulting in a cost efficient drilling program. Data collected during this project indicates that the northern Diamond Valley area generally contains materials of low hydraulic conductivities.

#### RECOMMENDATIONS

The District should continue with the collection of water quality and water level data from each of the new monitoring wells and from the previously installed wells at regularly scheduled intervals. After evaluation of the time series data from the wells the District will be able to determine the type of additional data that is required for designing the proposed irrigation fields and containment structures.

Evaluation and maintenance of the monitoring wells in Diamond Valley should occur regularly. This should include sounding the lowest screened intervals and semiquantitative pumping tests, if necessary, to assure that the wells are in direct communication with the water bearing zone associated with the screened intervals. Since the water level in well ACMW-09S has been dry and is commonly recorded within two feet of the lowest screen the well should be evaluated to determine what water levels are representative of the adjacent saturated material. A sump caused by the end plug on the casing or inadequate development of the lowest screen interval could provide a water level that is not representative of the water table. Ongoing maintenance of the wells in the well field can include removal of fill that might have accumulated in the well casing, repair of protective casing and installation of bollards around wells (if heavy equipment activity is anticipated).

Collection of baseline data down gradient of the proposed irrigation fields at ACMW-11 and ACMW-09N, should provide adequate data to identify water quality changes in the shallow alluvial zone. The influence of water placed in the containment field on these monitoring wells will be dependent on where in the containment field the water is placed, local permeability within the containment fields, seasonal and annual groundwater conditions and the distribution of surface water through the ditches in the area. Since the northwest portion of the infiltration fields occur within 1/8 mile of a topographic divide hydraulic mounding from infiltration at the irrigation fields could cause groundwater to flow radially away from the irrigation fields from the southwest to the northwest. This could reverse the direction of groundwater flow resulting in groundwater flow from the irrigation field flowing toward ACMW-12. Water quality from the screened interval of ACMW-12 may not change even if the gradient direction reverses because of the thick impermeable zone above the screen interval may not allow infiltration to the lower alluvial zone.

April 3, 2009 Page 12

Understanding the impacts from irrigation water to the local hydrogeology will require careful evaluation of the seasonal water level data. Data sets could include periods where water from the ditch network is temporarily rerouted to develop relationships between surface water and the alluvial water bearing zones. A better understanding of the existing relationships between surface water and the shallow alluvial zone will assist in understanding the effects of irrigation and or storage of reclaimed water.

South Tahoe Public Utility District Recycled Water Facilities Master Plan

Appendix I-c - Farr West Memorandum - Diamond Valley Containment Fields Nitrate Evaluation, Alpine County, CA

October 15, 2009

Ivo Bergsohn, Hydro-Geologist, South Tahoe Public Utility District 1275 Meadow Crest Drive South Lake Tahoe, CA 96150

Re: Diamond Valley Temporary Containment Fields Nitrate Evaluation, Alpine County, CA

Dear Mr. Bergsohn:

This letter provides a preliminary analysis regarding the probable annual changes in nitrate concentrations in the shallow water bearing zone underlying the proposed temporary storage site of up to 95 million gallons of treated water for a maximum of 100 days at South Tahoe Public Utilities District's temporary containment fields located in Diamond Valley, Alpine County, California.

Data collected during the November 2008 well installation and subsequent sample collection program is in accord with data that was collected during previous data collection efforts. The data indicate that water stored in the irrigation fields will have low infiltration rates into the vadose zone underlying these irrigation fields during periods of temporary containment of recycled water. The evidence collected that supports this conclusion includes low laboratory hydraulic conductivities from the most permeable soil horizons, low effective transmissivities observed during pumping for sampling and observations of significant silt and clay in the cores obtained during well installation. Layers of silts and clays that form aquitards and confining layers are situated between the most permeable zones that the samples were collected from for determination of hydraulic conductivity. The combination of these subsurface hydrogeologic conditions will contribute to low infiltration rates resulting in minimal mixing of recycled water that infiltrates from the temporary containment fields with water in underlying water bearing zones.

During nine months of the year the nitrate (measured as nitrogen) concentrations of the water that could be stored in the temporary containment fields for a period of up to 100 days ranges between 0.16 and 2.14 mg/L (previous 20 months). The nitrate concentration of the underlying water bearing zones ranges between 0.092 and 1.27 mg/L (2009). Thus, for nine months of the year infiltration of water from the temporary containment field would result less than significant increase in nitrate concentrations in the underlying water bearing zones. The mixing of water that infiltrates from storage during the months of late May to late July could result in minimal increases in the nitrate concentration. Using the highest, annual nitrate concentrations that have been discharged from the South Tahoe Public Utility District's treatment facilities during the past fifteen years for calculations, the concentration of the mixed waters would remain below the proposed action level of 7.0 mg/L.

In this portion of the project area there are highly variable site conditions and a level of uncertainty concerning environmental metrics such as hydraulic conductivity, hydraulic gradient and effective porosity. Additionally, the vadose zone is determined to be dynamic. For these reasons, a standard one dimensional mass flux equation was used for determining the "worse case" scenario for evaluating potential groundwater impacts from temporary containment of recycled water.

The "worse case" scenario for the temporary containment of water for 100 days was evaluated with a recycled water nitrate concentration of 1.53 mg/L. This is the median nitrate value for the previous 20 months of water delivery by South Tahoe Public Utilities to Alpine County, Ca. This scenario predicts a nitrate concentration of 2.16 mg/L (Table 1, including assumptions and uncertainties) from the nitrate mass of the infiltrate from temporary storage and groundwater from the upper water bearing zone. This value is sufficiently less than the proposed action level of 7.0 mg/L and the drinking water maximum contaminant level of 10.0 mg/L.

Based on the significance levels presented in the South Tahoe Public District Recycled Water Facilities EIR, I would recommend proceeding with implementation of the temporary containment fields with concurrent collection of data to allow for future significant modeling efforts with limited assumptions. The data collected during a temporary containment of recycled water could provide sufficient data for the calibration of numerical modeling for determination of effects of concentrations and duration of temporary containment.

Should you have any questions or require any additional information regarding this report please contact Kirk Swanson by phone at (775) 853-7257.

Best Regards,

Kirk Swanson, Ph.D., P.G.# 6272, C.Hg. #340

Re: Proposed Changes to the Alpine County Ground Water Monitoring Program (LRWQCB Monitoring and Reporting Program No. R6T-2004-0010; WDID No. 6A095900700)

Dear Mr. Tucker:

The following information is provided to the Lahontan Regional Water Quality Control Board (LRWQCB) in follow-up to the December 22, 2008 meeting between yourself and South Tahoe Public Utility District staff regarding District recommendations to improve the Groundwater Monitoring Program in Alpine County, CA (ACGMP). These recommendations concern changes to the existing groundwater monitoring network, including:

- 1. The inclusion of six (6) existing groundwater wells into the ACGMP;
- 2. The removal of six (6) private wells and two (2) District monitoring wells presently included in the ACGMP; and
- 3. The addition of eight (8) future sites for groundwater well construction proposed for later inclusion to the ACGMP.

When completed, these changes would increase the total number of groundwater wells in the ACGMP from sixteen (16) to twenty-two (22). The District believes that the recommended changes will improve the capability of the monitoring network to collect groundwater data that can be used to better evaluate potential changes in water quality from present and future uses of recycled wastewater in Alpine County, CA.

# 1 BACKGROUND

#### 1.1 Existing Groundwater Well Network

The District has been performing groundwater monitoring in Alpine County since 1981. The purpose of the monitoring is to provide adequate water quality data to determine whether the use of recycled wastewater is having a detrimental effect on the groundwater resources in Alpine County. The wells currently used for groundwater monitoring include seven (7) private wells and nine (9) shallow groundwater monitoring wells. The private wells selected for monitoring were based on recommendations provided by the USDA Natural Resource Conservation Service (NRCS) as part of their 1980 study to determine whether recycled wastewater could be safely reused in Alpine County. The shallow groundwater monitoring wells were installed by the District in 1988 as part of additions to the recycled wastewater conveyance system. The locations of these wells are shown in Figure 1. Available construction details for these wells are listed in Table 1.

#### 1.2 DRI Investigation

Over the past 15 years, five of the private wells (GW-04, GW-05, GW-07, GW-08, and GW-11) and one shallow groundwater monitoring well (ACMW-04) have shown increasing trends in nitrate (NO<sub>3</sub>) concentration. In 2006, the Desert Research Institute (DRI) performed a reconnaissance level investigation using site visits and a review of historical data to determine if there were simple or likely reasons for the observed NO<sub>3</sub> concentration trends in these wells (DRI, 2006). Findings from this investigation showed that the source of NO<sub>3</sub> contamination in the private wells is likely attributed to a combination of factors including: poor well construction (GW-04, GW-05, GW-07); recycled wastewater irrigation practices on private lands (GW-04, GW-05); livestock grazing practices (GW-04); and contamination by local septic systems (GW-07, GW-08). Observed NO<sub>3</sub> concentration trends in ACMW-04 and GW-11 were found generally to be less than 5 mg/L and were not a cause for concern.

#### 1.3 Alisto Evaluation

In 2008, Alisto Engineering (Alisto) conducted an evaluation to determine the adequacy of the existing monitoring program in collecting data to assess the impact of using recycled wastewater for pasture crop irrigation on surface water, groundwater and soil resources in Alpine County (Alisto, 2008). Based on the results of water level monitoring and evaluation of available data, Alisto provided recommendations that included:

- Modification of wellhead construction for improved protection, security and accessibility (GW-03, GW-04, GW-08, ACMW-02N, ACMW-02S, ACMW-03W);
- Destruction of two monitoring wells (ACMW-04W and ACMW-06N) that are no longer included in the monitoring network or considered to be redundant for use in monitoring; and
- Addition of seventeen (17) new shallow groundwater monitoring wells installed in two phases to ensure collection of reliable data.

# 2 GROUNDWATER FLOW CHARACTERIZATION

A major portion of the Alisto effort was devoted to the collection of surveyed groundwater well location and measuring point elevation data and groundwater level data for use in evaluating groundwater flow patterns. The interpreted patterns could then be used to assess the adequacy of existing and possible future groundwater well sites for monitoring potential changes in water quality resulting from the use of recycled wastewater. Data used for groundwater flow interpretation consisted of water level measurements collected from eight of the District's shallow groundwater monitoring wells included in the existing groundwater monitoring network (ACMW-01AW, ACMW-01BE, ACMW-02N,

ACMW-02S, ACMW-03, ACMW-04, ACMW-06N and ACMW-06S ACMW-05) and six additional District groundwater monitoring wells installed in 2003 (ACMW-07S, ACMW-07D, ACMW-08S, ACMW-08D, ACMW-09S and ACMW-09D). These additional wells were installed as part of a hydrogeologic reconnaissance investigation of Diamond Valley (Brown and Caldwell, 2006) and are not currently part of the ACGMP.

#### 2.1 <u>Hydrogeologic Setting</u>

The irrigated properties and groundwater wells included in the Alpine County Groundwater Monitoring Program are spread across an area of about 10.5 square miles that includes portions of Diamond Valley, Dutch Valley, Wade Valley and the south end of the Carson Valley, south of the California-Nevada stateline. The surface geology through this area has been mapped by Armin and John (1983) and geologic interpretations of major rock types used through this section are taken from this source (USGS Misc. Inv. Series Map I-1424). Figure 2 shows the consolidated bedrock areas consisting of plutonic and volcanic rocks that bound unconsolidated alluvial and glacial deposits through the valley areas.

Plutonic rocks outcrop along the west side of the subject area along the steep eastern slopes of the Carson Range [above an elevation of about 5800 feet mean sea level (fmsl)] and bound the western margin of the Carson Valley. These generally consist of Jurassic and Triassis andesites and dacites and Creatceous granites and granodiorites. These consolidated rocks are believed to be relatively impermeable to groundwater flow.

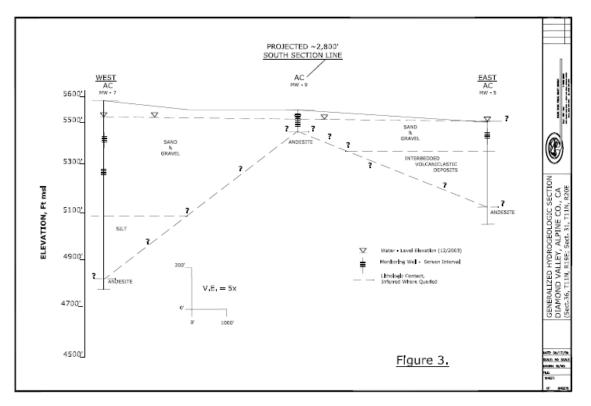

Volcanic rocks outcrop in the southeast corner of the subject area and form the low-lying hills occurring between Indian Creek and the East Fork of the Carson River bounding the east margin of Diamond Valley and Dutch Valley and the southeast margin of Carson Valley. Volcanic rocks also form the low lying hills between Diamond and Wade Valleys. These generally consist of Tertiary andesitic volcanics composed of interbedded andesitic lahars, stratified tuffaceous sandstone, and conglomerate with minor andesite. Some groundwater flow is believed to flow through Tertiary semi-consolidated sediments. These are typically found in the foothills west of the Pine Nut Mountains, northeast of the subject area. Generally, the consolidated Tertiary volcanic rocks described above are believed to be relatively impermeable to groundwater flow. However, the geologic log for the Celio Ranch Well in Wade Valley (GW-04) suggests that where sufficiently fractured, Tertiary volcanics may produce sufficient quantities of groundwater for domestic use.

Quaternary alluvial and glacial deposits lie upon the downthrown side (or hanging wall) of the Genoa fault, an active Sierra Nevada frontal fault, occurring along the mountain front of the Carson Range. These include outwash, moraine and alluvial deposits that form: the eastward sloping alluvial fans between the Carson Range and the West Fork of the Carson River (WFCR); the valley floor on the

3/5/2009

west side of Diamond Valley; and the valley floor underlying Wade Valley and Dutch Valley. The east side of Diamond Valley is floored by younger Quaternary valley fill deposits. Quaternary alluvial fan, basin-fill, outwash and floodplain deposits underlie the valley floor at the south end of Carson Valley. The primary water-bearing units in the Carson Valley occur in the Quaternary alluvial deposits. Confined water-bearing zones through these deposits form the principal drinking water aquifers through the area.

Geologic logs from District monitoring wells drilled in Diamond Valley show that the upper portion of the subsurface is composed predominantly of alluvial deposits consisting of poorly-graded mixtures of medium to coarse granitic sands, gravels and boulders. Thin layers of clayey sand and silt are rare. Depending on location across the valley fine silt; tuffaceous sandstone and gravel; and volcanic lithic tuffs, welded tuffs and andesite are encountered below the upper sand and gravel deposits at depths varying from about 40 feet below ground surface (ft bgs) to as much as 480 ft bgs (Figure 3). These underlying deposits have been mapped as Tertiary Volcanics (Armin and John, 1983). Geologic mapping suggests that District groundwater wells installed in Wade Valley and Carson Valley were completed in unconsolidated alluvial fan or basinfill deposits. Boring logs describing these deposits were not found for these wells.

**Figure 3.** Generalized Hydrogeologic Section, Diamond Valley, Alpine Co., CA; Sect. 36, T 11N, R19E; Sect. 31, T 11N, R20E

The West Fork of the Carson River (WFCR) is the dominant hydrologic feature through the project area. The WFCR enters from the southwest and flows northward toward the Carson Valley. The USGS reported the average annual stream flow of the WFCR near Woodfords, CA at 75,600 acre-feet per year (acre-ft/yr) for water years 1940-2005. The WFCR is believed to be a gaining stream along its reaches through the subject area. Therefore, the bed elevation can be used to approximate shallow groundwater elevation along the stream bed.

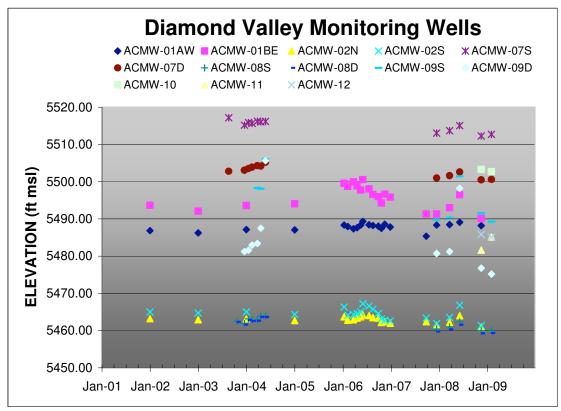

Indian Creek is tributary to the WFCR and also enters from the southwest flowing east toward the east end of Diamond Valley and then north through Dutch Valley along the toe of the Tertiary volcanics in the southeast portion of project area. Average annual stream flow for Indian Creek has been estimated at 5,100 acre-ft/yr for water years 1940-2005 (Maurer and Berger, 2007). Indian Creek is also believed to be a gaining stream along its reaches through the subject area.

Streamflow from the WFCR is diverted for irrigation use to Snowshoe Thompson Ditch No.1 and the Millich Ditch Diversion, downstream of the USGS gaging station near Woodfords, CA. Total diversions are reported to average 5,900 acreft/yr for water years 1993 – 2003 (Maurer and Berger, 2007). Ditch losses from this ditch system drains to Indian Creek as return flows and is a source of groundwater recharge through the area.

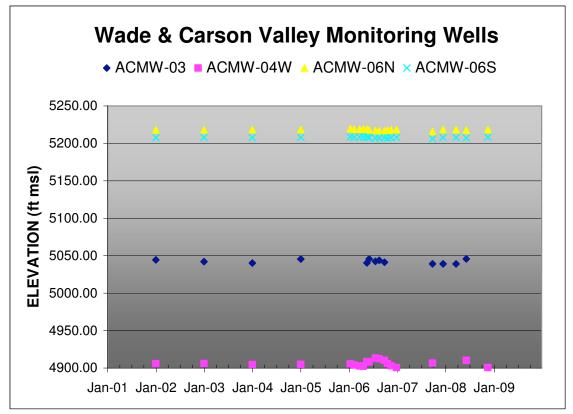

Water resource investigations completed by the USGS show that groundwater characteristically flows from the mountain fronts bordering the east and west margins of the basin toward the center of the Carson Valley and then northward along the longitudinal axis of the valley concordant with the WFCR. Groundwater depths near the mountain fronts are believed to be on the order of 100 to 200 ft bgs. Groundwater depths progressively decline toward the valley floor where it is found at depths on the order of 5 ft bgs or less (Maurer, 1986; Maurer and Berger, 2007).

Available hydrogeologic information collected by the District suggests that the uppermost zone of water saturation occurs within the alluvial deposits under varying aquifer conditions. Results from geologic logging, aquifer testing and water level monitoring, suggest that the uppermost portion of the zone of saturation is confined on the west side of Diamond Valley (ACMW-07). The uppermost portion of the zone of saturation is unconfined at monitoring well locations near the center of Diamond Valley (ACMW-10 and ACMW-11) and near Indian Creek (ACMW-01AW, ACMW-01BE, ACMW-02N and ACMW-02S). Perched water has been identified overlying the zone of saturation in the north half of Diamond Valley (ACMW-09S). The uppermost portion of the zone of saturation below the perched water horizon is believed to be either semi-confined (ACMW-09D) or confined (ACMW-12). Groundwater level data collected from District groundwater wells (ACMW-06N and ACMW-06S) suggest that the uppermost portion of the zone of saturation may be semi-confined in Wade

Valley. Groundwater level data collected from District groundwater wells in Carson Valley (ACMW-04) suggests that the uppermost portion of the zone of saturation is unconfined. The water table is typically found within 20 feet of land surface. Hydrographs showing water level elevations measured in District wells in Diamond Valley; and in Wade and Carson Valleys are provided as Figures 4 and 5, respectively.

**Figure 4.** Water level elevations measured in District Monitoring Wells in Diamond Valley, CA.

#### 2.2 Groundwater Flow

Mapping of groundwater elevations inferred from surface water features (springs, streams and lake elevations); alluvial-bedrock contact elevations along the margins of the basin; and groundwater level elevations measured at twelve of the District's groundwater wells in November 2008 (ACMW-01AW, ACMW-01BE, ACMW-02N, ACMW-02S, ACMW-04W, ACMW-06N, ACMW-07S, ACMW-08S, ACMW-09S, ACMW-10, ACMW-11 and ACMW-12) were used to develop a conceptual model showing regional groundwater flow patterns across the subject area (Figure 6). In general, groundwater moves from mountain front areas at higher elevations along the basin margins toward discharge areas at lower elevations occurring along surface water reaches along the valley floor. Groundwater depths at the mountain fronts were inferred as follows:

- 120 feet below the contact elevation between plutonic rocks and unconsolidated alluvial and glacial deposits along the mountain front of the Carson Range on the west side of the subject area.
- 60 feet below the contact elevation between consolidated volcanic rocks and unconsolidated alluvial and glacial deposits, along the southeast portion of the subject area; and

• 30 feet below the contact elevation between consolidated volcanic rocks and unconsolidated alluvial deposits bordering the Tertiary volcanics between Diamond Valley and Wade Valley.

Groundwater inflow toward Diamond Valley is inferred to be from the mountain front along the east slopes of the Carson Range, south and west of Diamond Valley. Mountain front recharge from the southwest flows northeast toward Diamond Valley. Through Diamond Valley, groundwater flow directions are believed to diverge and are generally directed to the northwest toward the West WFCR near the west side of the valley and are generally directed to the eastnortheast toward Indian Creek near the east side of the valley. The Tertiary volcanic rocks forming the low-lying hills forming the north margin of the valley are believed to form a low permeability boundary that accentuates this flow divergence through Diamond Valley.

Groundwater inflow toward Carson Valley is inferred to be from the mountain front located along the east slopes of the Carson Range, west and north of Paynesville, CA and from the mountain front located along the west slopes of the Tertiary volcanics, south of Mud Lake. Mountain front recharge from the west margin of the basin is generally directed to the east toward the valley floor and then northeast along the WFCR. Mountain front recharge from the east margin of the basin is generally directed west and northwest toward the valley floor and then north along the WFCR.

Groundwater inflow toward Dutch Valley is inferred to be from the east end of Diamond Valley and from mountain front along the west slopes of the volcanic rocks, east of the Woodfords Indian Community. Groundwater inflow from Diamond Valley to Dutch Valley is directed north and northeast through unconsolidated sediments occurring within the Indian Creek stream valley. Mountain front recharge is also believed to contribute to groundwater inflow and is inferred to be directed northwest across Dutch Valley toward the WFCR.

Wade Valley appears to be an area of limited groundwater inflow. Recharge to this valley is believed to be from a relatively limited catchment area defined by the crest of the consolidated volcanic rocks bounding the east, south and west sides of the valley.

# **3 PROPOSED GROUNDWATER WELL NETWORK**

Given the findings of the DRI Investigation and the evaluation of groundwater flow through the subject area, the District recommends that the LRWQCB change the designated groundwater wells presently used in the ACGMP (Figure 1). The purpose of these changes is to improve the capability of the monitoring network to collect groundwater data that can be used to better evaluate potential changes in water quality from present and future uses of recycled wastewater in Alpine County.

Figure 7 shows the locations of groundwater wells recommended for use in an improved groundwater well network. The needed changes to transform the existing well network involve: the inclusion of six (6) existing groundwater wells installed by the District in 2003 and 2008; the removal of eight (8) groundwater wells presently part of the ACGMP; and the addition of eight (8) sites for groundwater well construction proposed for future inclusion into the ACGMP. Discussion of these recommended changes is provided in the following section.

#### 3.1 Groundwater Well Additions

The District has installed nine groundwater wells in Diamond Valley for the collection of hydrogeologic information that are currently not part of the ACGWMP (Figure 6). General well construction details for these wells are summarized in Table 2.

| Table 2. General well construction details for existing groundwater wells |  |
|---------------------------------------------------------------------------|--|
| proposed for addition to the ACGWMP.                                      |  |

ACMW-07S is located in an inferred up-gradient location on the west side of Diamond Valley within the NE <sup>1</sup>/<sub>4</sub>, SW <sup>1</sup>/<sub>4</sub> of Section 36, T 11N, R19E. Logging, aquifer testing and water level elevation data suggest that the uppermost portion of the zone of water saturation is confined through this area. ACMW-07S is proposed as a control well for the collection of background water quality samples for Diamond Valley. Collection of water quality samples from ACMW-07S would also supplement water quality data provided by the Diamond Valley School Well (GW-11) which is screened through a similar portion of the saturated water zone. ACMW-08N is located in an inferred down-gradient location on the east side of Diamond Valley within the SW 1/4, NE 1/4 of Section 35, T 11N, R20E. Logging and water level elevation data suggest that this well is screened within the uppermost semi-confined interval of the saturated water zone. The saturated water zone along the east side of Diamond Valley is believed to be multi-layered. Groundwater samples collected from this well will be used to supplement water quality data presently collected at ACMW-02N, -02S from the overlying unconfined portion of the saturated water zone.

ACMW-09S and -09D form a shallow and deep well pair located near the north margin of Diamond Valley near the SE corner of Section 25, T 11N, R19E. The District is proposing to use the area south of this well pair for the land application and emergency discharge and containment of reclaimed wastewater (Phase I Irrigation Field). Borehole logging, well development and water level elevation data suggests that the shallow well (ACMW-09S) is screened through a perched water zone above the zone of water saturation. The deeper well (ACMW-09D) is screened through the underlying zone of water saturation, occurring in unconsolidated sediments above volcanic bedrock. The zone of water saturation is believed to be semi-confined through this area. Groundwater samples are proposed to be collected solely from ACMW-09D to monitor water quality changes through the semi-confined water zone.

ACMW-10 is located in the SW <sup>1</sup>/<sub>4</sub>, NE <sup>1</sup>/<sub>4</sub> of Section 36, T 11N, R19E in an inferred up-gradient location with respect to the District's proposed Phase I Irrigation Fields. Logging and water level elevation data show that the zone of water saturation is unconfined through this area with the well screened across the water table. Groundwater samples collected from this well will be used to provide background water quality data for the unconfined portion of the saturated water zone.

ACMW-11 is located in the SW <sup>1</sup>/<sub>4</sub>, NW <sup>1</sup>/<sub>4</sub> of Section 31, T 11N, R20E in an inferred down-gradient location with respect to the District's proposed Phase I Irrigation Fields. Logging and water level elevation data show that the zone of water saturation is unconfined through this area with the well screened across the water table. Groundwater samples collected from this well will be used to monitor potential water quality changes from use of the Phase I Irrigation Fields through the unconfined portion of the saturated water zone.

ACMW-12 is located in the NW <sup>1</sup>/<sub>4</sub>, NE <sup>1</sup>/<sub>4</sub> of Section 36, T 11N, R19E in an inferred down-gradient location with respect to the District's proposed Phase I Irrigation Fields. Logging data shows that perched water is present above the zone of water saturation. The uppermost portion of the saturated water zone is believed to be confined through this area. ACMW-12 will be used to monitor potential water quality changes in the uppermost confined portion of the saturated water zone.

#### 3.2 Groundwater Well Removals

The District is proposing to remove eight (8) existing groundwater wells from the ACGMP. Six of these are private wells that for several reasons no longer provide useful water quality information for the ACGMP. The remaining two are District monitoring wells that are inadequate for collecting groundwater samples from the uppermost portion of the zone of water saturation. Reasons for the removal of these wells from the monitoring network are summarized in Table 3.

| WELL I.D. | Reason(s) for Removal                                                |
|-----------|----------------------------------------------------------------------|
| GW-03     | Private well located outside recycled wastewater use area; well      |
|           | construction information is unknown; sounding port requires repair.  |
| GW-04     | Ambiguous water quality data due to poor well construction; recycled |
|           | wastewater irrigation practices; and grazing practices.              |
| GW-05     | Ambiguous water quality data due to poor well construction; and      |
|           | recycled wastewater irrigation practices.                            |
| GW-07     | Ambiguous water quality data due to poor well construction and       |
|           | contamination by household septic system.                            |
| GW-08     | Ambiguous water quality data due to poor well construction and       |
|           | contamination by household septic system.                            |
| GW-14     | Private well located outside recycled wastewater use area; well      |
|           | construction information is unknown; sounding port requires repair.  |
| ACMW-03   | Inadequate well depth for shallow groundwater monitoring.            |
| ACMW-05   | Inadequate well depth for shallow groundwater monitoring.            |

Table 3. Groundwater wells recommended for removal from the ACGMP.

GW-03 is a private well located along the west margin of Dutch Valley approximately 1-mile north northeast of the Diamond Valley Ditch Inverted Siphon, at the east end of Diamond Valley. The well is far-away from areas where recycled wastewater is conveyed or used. Because of its distal location, this well is not useful for ground water monitoring and is recommended for removal from the ACGMP.

GW-04 is a private well located in Wade Valley, near Diamond Valley Road. Findings from the DRI Investigation suggest that the lack of a sanitary seal, occurrence of a treated effluent ditch within 20 feet of the wellhead and past grazing of cattle near the wellhead likely contributed to the increase in NO<sub>3</sub> concentrations observed in GW-04 during the mid 1990s. Poor well construction obfuscates the utility of this well for groundwater monitoring and is recommended for removal from the ACGMP.

GW-05 is a private well located in the front yard of the Neddenriep Ranch House in Carson Valley. Findings from the DRI Investigation suggest that the lack of a sanitary seal, occurrence of a treated effluent ditch within 2 feet of the wellhead and flood irrigation at the ranch house likely contributed to the increase in NO<sub>3</sub>

concentrations observed in GW-05. Poor well construction obfuscates the utility of this well for groundwater monitoring and is recommended for removal from the ACGMP.

GW-07 is a private well located at the Gansberg Ranch House more than two miles west of the Upper Fredricksburg Ditch. The site is situated more than two miles upgradient with respect to any areas where recycled wastewater is conveyed or used. Findings from the DRI Investigation suggest that the lack of a sanitary seal and proximity within 200 feet of a septic leach field at the ranch house likely contributed to the increase in NO<sub>3</sub> concentrations observed in GW-07. Poor well construction and location far-away from areas using or conveying recycled wastewater obfuscates the utility of this well for groundwater monitoring and is recommended for removal from the ACGMP.

GW-08 is a private well located at the Arant Ranch House, approximately 200 feet west of the Upper Fredricksburg Ditch. The site is situated within an area irrigated with recycled wastewater. Findings from the DRI Investigation suggest shallow groundwater and proximity of a septic tank located within 100 feet of the wellhead likely contributed to the increase in NO<sub>3</sub> concentrations observed in GW-08. Groundwater contamination from a local septic system obfuscates the utility of this well for groundwater monitoring and is recommended for removal from the ACGMP.

GW-14 is a private well located in the Sierra Pines Trailer Park along the mountain front of the Carson Range, approximately one-half mile west of the southwest margin of Diamond Valley. The well is situated approximately 1.5 miles west from areas where recycled wastewater is conveyed or used. Construction information for this well was not found. GW-14 is the designated control well for the ACGMP. Although the location is appropriate for use as a control well for Diamond Valley, the District recommends that this well be removed from the ACGMP and replaced with GW-11.

ACMW-03 is a shallow monitoring well located on the Bruns Ranch near the south bank of the Upper Fredricksburg Ditch near Highway 88. This well is the shallowest of the groundwater wells and has been dry for about twenty five percent of the ACGMP sampling events. Water quality data from GW-03 is believed to be representative of seepage from the adjoining ditch and may not be representative of water quality in the uppermost zone of water saturation. The District therefore recommends that this well be removed from the ACGMP.

ACMW-05 is a shallow monitoring well located on the Dressler Ranch within the On-Farm Emergency Disposal site. This well is very shallow and has been dry during all of the ACGMP sampling events. Water quality samples from ACMW-05 are not likely to be representative of water quality in the uppermost zone of water saturation. Therefore it is recommended that this well be removed from the ACGMP.

#### 3.3 Future Groundwater Well Sites

The District is recommending the installation of eight (8) new shallow groundwater wells for addition to the ACGMP. The recommended well sites were selected using relative positions with respect to the reclaimed wastewater application areas and regional patterns of groundwater flow; and accessibility for future drilling, well construction and groundwater monitoring tasks. The majority of these sites are located within public right-of-way that will require permitting with Alpine County or other relevant agencies. Several of these sites (PW-05, PW-06, PW-11 and PW-12) are located on private lands that will require access agreements with applicable property owners. Figure 7 shows the locations of the recommended well sites. General descriptions of these sites are summarized in Table 4.

| SITE  | LOCATION                              | DESCRIPTION                                                                                                                                                         | APPLICATION                       | NOTES                                                                                                    |
|-------|---------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------|----------------------------------------------------------------------------------------------------------|

#### **Table 4.** Recommended sites for future groundwater well installations.

|       |                                      | Neva Stateline.                                                                                                                 |                                   | area.                                                                                                      |
|-------|--------------------------------------|---------------------------------------------------------------------------------------------------------------------------------|-----------------------------------|------------------------------------------------------------------------------------------------------------|
| PW-19 | SE ¼, NW ¼,<br>Sec 32,<br>T11N, R20E | East end of Diamond<br>Valley, downstream of<br>Diamond Valley Ditch<br>inverted siphon.                                        | Recycled<br>Wastewater            | Down-gradient<br>location near<br>Indian Creek,<br>replacing GW-03.                                        |
| PW-20 | SW ¼, SE ¼,<br>Sec 18,<br>T11N, R20E | West shoulder of<br>Chambers Road, near<br>its intersection with<br>Diamond Valley Road<br>at West Fork Carson<br>River bridge. | Blended<br>Recycled<br>Wastewater | Up-gradient<br>(Control)<br>location, up-<br>gradient of<br>Diamond Ditch<br>Pipeline,<br>replacing GW-08. |

PW-04 is located within the right-of-way along the south shoulder of River Ranch Road, between Highway 88 and Chambers Road. Access to the site is excellent along a paved roadway. The site is situated near the south end of the Double Bar W Ranch and is down-gradient with respect to properties using blended recycled wastewater between Paynesville and River Ranch Road. It is situated upgradient with respect to properties using blended recycled wastewater north of River Ranch Road.

PW-05 is located on private property along the west shoulder of Chambers Road, east of the Neddenriep Ranch. Access to the site is satisfactory along an unpaved unimproved road. The site is situated along the east margin of the ranch, down-gradient with respect to properties using blended recycled wastewater. The future groundwater well proposed for this site is recommended to replace GW-05.

PW-06 is located on private property along the west shoulder of Chambers Road, at the California-Nevada stateline. Access to the site is satisfactory along an unpaved unimproved road. The site is situated furthest down-gradient with respect to properties using blended recycled wastewater in Carson Valley.

PW-07 is located within the right-of-way along the south shoulder of School House Road, west of the Upper Fredricksburg Ditch. Access to the site is excellent along a paved roadway. The site is situated up-gradient with respect to the irrigation ditch and properties using blended recycled wastewater in Carson Valley and will be used as a control well for irrigated lands west of the WFCR. The future groundwater well proposed for this site is recommended to replace GW-07.

PW-11 is located along an unimproved road, near the east margin of the Brooke property. Access to the site is satisfactory along an unpaved unimproved road. The site is situated down-gradient with respect to the On-farm Emergency Disposal site and up-gradient with respect to the portion of the Brooke property using reclaimed wastewater and will be used as a control well for irrigated lands east of the WFCR. PW-12 is located along an unimproved road, near the east margin of the Brooke property at the California-Nevada stateline. Access to the site is acceptable, but could use brush removal for accessibility for well drilling equipment. The site is situated down-gradient with respect to the Brooke Ditch and up-gradient with respect to the property using reclaimed wastewater.

PW-19 is located along a private unimproved road, near the north bank of Indian Creek, east of the Diamond Ditch Inverted Siphon. Access to the site is satisfactory, but may be subject to flooding from Indian Creek. The site is situated down-gradient with respect to the Diamond Ditch Inverted Siphon and irrigated lands in Diamond Valley.

PW-20 is located near the Paynesville Bridge, within the right-of-way along the west shoulder of Chambers Road, south of the Diamond Valley Ditch Pipeline. Access to the site is excellent along a paved roadway. The site is situated up-gradient with respect to the west end of the pipeline and will be used as a control well for irrigated lands using blended recycled wastewater between Paynesville and River Ranch Road. The future groundwater well proposed for this site is recommended to replace GW-08.

Construction details for future well installations will be provided in a future work plan developed to satisfy permitting requirements. This workplan will be developed after the recommended changes have been accepted by the LRWQCB for inclusion in the ACGMP.

Please contact me at your earliest convenience, should you require any further information regarding the changes proposed to the District's groundwater monitoring network.

Sincerely,

lvo Bergsohn, P.G., C.Hg. Hydro-Geologist

Subject: Species List for STPUD Recycled Water Facilities Master Plan EIR

Dear: Mr.

We are sending this official species list in response to your September 16, 2008 request for information about endangered and threatened species. The list covers the California counties and/or U.S. Geological Survey 7<sup>1</sup>/<sub>2</sub> minute quad or quads you requested.

Our database was developed primarily to assist Federal agencies that are consulting with us. Therefore, our lists include all of the sensitive species that have been found in a certain area *and also ones that may be affected by projects in the area*. For example, a fish may be on the list for a quad if it lives somewhere downstream from that quad. Birds are included even if they only migrate through an area. In other words, we include all of the species we want people to consider when they do something that affects the environment.

Please read Important Information About Your Species List (below). It explains how we made the list and describes your responsibilities under the Endangered Species Act.

Our database is constantly updated as species are proposed, listed and delisted. If you address proposed and candidate species in your planning, this should not be a problem. However, we recommend that you get an updated list every 90 days. That would be December 15, 2008.

Please contact us if your project may affect endangered or threatened species or if you have any questions about the attached list or your responsibilities under the Endangered Species Act. A list of Endangered Species Program contacts can be found at <a href="http://www.fws.gov/sacramento/es/branches.htm">www.fws.gov/sacramento/es/branches.htm</a>.

Endangered Species Division

## Federal Endangered and Threatened Species that Occur in or may be Affected by Projects in the Counties and/or U.S.G.S. 7 1/2 Minute Quads you requested

Document Number: 080916102854 Database Last Updated: January 31, 2008

Quad Lists

## Listed Species

Fish

Oncorhynchus (=Salmo) clarki henshawi Lahontan cutthroat trout (T)

**Candidate Species** 

#### Amphibians

Bufo canorus Yosemite toad (C)

Rana muscosa

mountain yellow-legged frog (C)

#### Mammals

Martes pennanti fisher (C)

#### Quads Containing Listed, Proposed or Candidate Species:

MARKLEEVILLE (506A) CARTERS STATION (521C) MINDEN (522A) WOODFORDS (522D)

# **County Lists**

No county species lists requested.

## Key:

- (E) Endangered Listed as being in danger of extinction.
- (T) Threatened Listed as likely to become endangered within the foreseeable future.

(P) Proposed - Officially proposed in the Federal Register for listing as endangered or threatened.

(NMFS) Species under the Jurisdiction of the <u>National Oceanic & Atmospheric Administration Fisheries Service</u>. Consult with them directly about these species.

Critical Habitat - Area essential to the conservation of a species.

(PX) Proposed Critical Habitat - The species is already listed. Critical habitat is being proposed for it.

(C) Candidate - Candidate to become a proposed species.

(V) Vacated by a court order. Not currently in effect. Being reviewed by the Service.

(X) Critical Habitat designated for this species

# Important Information About Your Species List

How We Make Species Lists

We store information about endangered and threatened species lists by U.S. Geological Survey 7<sup>1</sup>/<sub>2</sub> minute quads. The United States is divided into these quads, which are about the size of San Francisco.

The animals on your species list are ones that occur within, **or may be affected by** projects within, the quads covered by the list.

- Fish and other aquatic species appear on your list if they are in the same watershed as your quad or if water use in your quad might affect them.
- Amphibians will be on the list for a quad or county if pesticides applied in that area may be carried to their habitat by air currents.
- Birds are shown regardless of whether they are resident or migratory. Relevant birds on the county list should be considered regardless of whether they appear on a quad list.

## Plants

Any plants on your list are ones that have actually been observed in the area covered by the list. Plants may exist in an area without ever having been detected there. You can find out what's in the surrounding quads through the California Native Plant Society's online <u>Inventory of Rare and Endangered Plants</u>.

## Surveying

Some of the species on your list may not be affected by your project. A trained biologist or botanist, familiar with the habitat requirements of the species on your list, should determine whether they or habitats suitable for them may be affected by your project. We recommend that your surveys include any proposed and candidate species on your list.

For plant surveys, we recommend using the <u>Guidelines for Conducting and Reporting</u> <u>Botanical Inventories</u>. The results of your surveys should be published in any environmental documents prepared for your project.

## Your Responsibilities Under the Endangered Species Act

All animals identified as listed above are fully protected under the Endangered Species Act of 1973, as amended. Section 9 of the Act and its implementing regulations prohibit the take of a federally listed wildlife species. Take is defined by the Act as "to harass, harm, pursue, hunt, shoot, wound, kill, trap, capture, or collect" any such animal.

Take may include significant habitat modification or degradation where it actually kills or injures wildlife by significantly impairing essential behavioral patterns, including breeding, feeding, or shelter (50 CFR §17.3).

# Take incidental to an otherwise lawful activity may be authorized by one of two procedures:

• If a Federal agency is involved with the permitting, funding, or carrying out of a project that may result in take, then that agency must engage in a formal <u>consultation</u> with the Service.

During formal consultation, the Federal agency, the applicant and the Service work together to avoid or minimize the impact on listed species and their habitat. Such consultation would result in a biological opinion by the Service addressing the anticipated effect of the project on listed and proposed species. The opinion may authorize a limited level of incidental take.

• If no Federal agency is involved with the project, and federally listed species may be taken as part of the project, then you, the applicant, should apply for an incidental take permit. The Service may issue such a permit if you submit a satisfactory conservation plan for the species that would be affected by your project.

Should your survey determine that federally listed or proposed species occur in the area and are likely to be affected by the project, we recommend that you work with this office and the California Department of Fish and Game to develop a plan that minimizes the project's direct and indirect impacts to listed species and compensates for project-related loss of habitat. You should

## **Critical Habitat**

When a species is listed as endangered or threatened, areas of habitat considered essential to its conservation may be designated as <u>critical habitat</u>. These areas may require special management considerations or protection. They provide needed space for growth and normal behavior; food, water, air, light, other nutritional or physiological requirements; cover or shelter; and sites for breeding, reproduction, rearing of offspring, germination or seed dispersal.

Although critical habitat may be designated on private or State lands, activities on these lands are not restricted unless there is Federal involvement in the activities or direct harm to listed wildlife.

If any species has proposed or designated critical habitat within a quad, there will be a separate line for this on the species list. Boundary descriptions of the critical habitat may be found in the Federal Register. The information is also reprinted in the Code of Federal Regulations (50 CFR 17.95). See our <u>critical habitat page</u> for maps.

## **Candidate Species**

We recommend that you address impacts to candidate species. We put plants and animals on our candidate list when we have enough scientific information to eventually propose them for listing as threatened or endangered. By considering these species early in your planning process you may be able to avoid the problems that could develop if one of these candidates was listed before the end of your project.

## Species of Concern

The Sacramento Fish & Wildlife Office no longer maintains a list of species of concern. However, various other agencies and organizations maintain lists of at-risk species. These lists provide essential information for land management planning and conservation efforts. <u>More info</u>

## Wetlands

If your project will impact wetlands, riparian habitat, or other jurisdictional waters as defined by section 404 of the Clean Water Act and/or section 10 of the Rivers and Harbors Act, you will need to obtain a permit from the U.S. Army Corps of Engineers. Impacts to wetland habitats require site specific mitigation and monitoring. For questions regarding wetlands, please contact Mark Littlefield of this office at (916) 414-6580.

## Updates

Our database is constantly updated as species are proposed, listed and delisted. If you address proposed and candidate species in your planning, this should not be a problem. However, we recommend that you get an updated list every 90 days. That would be December 15, 2008.

### Appendix L - Calculation Assumptions, Methodology and Results (Chapter 13)

### Appendix L - Air Pollutant Emissions Estimates

### L.1 Construction Phase

The construction emissions inventory is consistent with the methodologies established by the California Climate Action Registry (CCAR). In addition to well-established emission factors for certain activities and emission estimates based on similar activities in other representative communities; the URBEMIS and EMFAC emissions estimation software programs were used, as recommended by the California Air Resources Board.

This inventory was prepared as a worst-case analysis. For example, it assumes that all emissions from the project are "new," in the sense that, absent the development of the project, these emissions would not occur. Given the global nature of GHG emissions, "new" global GHG emissions are those caused by economic growth and population growth (births); local infrastructure development projects accommodate such growth.

As an example of why these are worst-case emissions, these emissions are estimated assuming that there are no reductions in GHG-generating activities over time. This is clearly unlikely, and presents a conservative analysis, given the expected reductions in GHG emissions from most activities that will take place over the years due to future regulations, greater public awareness and the likely increasing costs of energy.

The following construction phase equipment utilization activity assumptions are based on best judgement of a reasonable representative worst case day for project facility excavation and construction activities. As stated below, it was assumed that a maximum of two sites would be under construction at the same time. For each site four pieces of heavy construction equipment were assumed to be operating simultaneously for most or all of the construction day. In actual practice it is unusual for heavy equipment of operate simultaneously and nearly continuously on relatively restricted project sites during construction, but the calculation were based on those assumptions to determine the highest reasonably attainable emissions rates. A representative assumption of 10 construction personnel at each site was assumed - again this is a reasonable number of personnel to operate the equipment, supervise, inspect, etc. the construction activity. While the exact commuting distance of each worker cannot be accurately known. it was assumed that each worker would drive his own vehicle an average of 20 miles in each direction for commuting purposes.

The overall duration of construction activity is not known at this time. Construction will likely take place in phases over a number of years and take varying periods of time as infrastructure is needed. To assume a total number of worst case construction days on which to base total project-related construction GHG emissions at this time would be unduly speculative.

### L.1.1 Construction Equipment Daily Activity Assumptions:

- Two sites under construction simultaneously
- One water/haul truck (8 hours)
- One grader (6 hours)
- One rubber-tired dozer (6 hours)
- One tractor/loader/backhoe (7 hours)

• Ten construction workers at each site commuting in single-occupancy vehicles traveling 40 miles daily round trip

#### L.1.2 Calculation Tools:

- URBEMIS 2007 Version 9.2.4 for construction equipment emissions
- EMFAC2007 V2.3 Nov 1, 2006 or on road motor vehicle emissions

| Table L-1                                                 |      |       |       |      |       |        |          |

\* PM emissions include both dust and exhaust emissions.

### L.2 Operational Phase

The operational phase of the Master Plan Project is described in Section 2.12. The project includes includes two major features:

- Flood/Emergency Situations The project includes forty-nine acres of temporary 6-foot containment berms (worst case scenario water level) holding 294 acre-feet of water. It is assumed that there will be an average one flood/emergency situation per year, which will require the use on a single pump operating for a total of 24 days to pump all worst-case scenario waters back to Harvey Place Reservoir.
- Central Point Pivot Systems The project incorporates the NMP recommended maximum application rate of 66.75 inches per year. It is assumed that irrigation will be done from 5 central pivot systems 15 days per month for 8 months per year, or 5.57 acre-feet per year applied over a total of 120 days.

#### L.2.1 Operational Phase Equipment Daily Activity Assumptions:

- One water pump with 100 hp diesel engine operating continuously for 24 hours per day for a total of 24 days per year.
- Five electric-powered 25KW central pivot point irrigation systems each operating continuously for 24 hours per day for a total of 120 days per year per system, or a total of 600 operating days per year for five systems. The total electric use per day per system is therefore 600KWH or 3,000 KWH total daily for five systems. The total energy used during 600 total system operating days is 1,800,000 KWH or 1,800 MWH.

#### L.2.2 Calculation Tools:

- URBEMIS 2007 Version 9.2.4 for pump equipment emissions
- Greenhouse gas emissions (and sequestration) inventories are not available specifically for for the project region. Electricity is supplied to the project area by PG&E. As reported by PG&E (2007),

the carbon dioxide emissions rate of PG&E-owned electric generation was 44 pounds per megawatthour (lbs/MWh), while the independently certified CO<sub>2</sub> emissions rate associated with the power sold by PG&E to its customers was 489 lbs/MWh. The national average carbon dioxide emissions rate for power generation was approximately 1,363 lbs/MWh and the California average CO<sub>2</sub> emissions rate was approximately 879 lbs/MWh, as shown in Table L-3.

|                                                                                                                                     | Table L-2          |              |  |  |

\* PM emissions include both dust and exhaust emissions.

Assuming therefore that a total of 1,800 MWH of electric energy is used by the five central pivot point systems during one calendar year, then the total yearly CO<sub>2</sub> emissions would be 440.1 tons (equivalent to 363.7 metric tons).

### Appendix N - Component 11, 18, and 19 Project Level Environmental Analysis

### Appendix N - Guide to Project Level Analysis

To assist the reader in understanding the project-level analysis completed as part of the EIR, this appendix provides a summary for Project Components 11, 18 and 19. These three Project Components comprise Master Plan Projects 1, 2, 11 and 12, which are detailed on pages 9-61 through 9-64 and 10-77 through 10-78 of the *South Tahoe Public Utility District Recycled Water Facilities Master Plan - November 2009* (Stantec 2009). Projects 1, 2, 11 and 12 are analyzed at the project -level because of the need for expedited implementation to resolve the issues of inadequacy with the existing On-Farm Emergency Disposal System (page 13-100, Stantec 2009).

### **N.1 Project Component Descriptions**

## N.1.1 Project Component 11 - Construct Irrigation Fields With Pumping Back to HPR

The following project description is on page 2-14 of section 2.6.2.

The District will construct seven irrigation fields, two to contain excess and emergency flows from HPR and five to irrigate with both fresh and recycled water. The two containment fields will be constructed so that the temporarily contained recycled water could be pumped back to HPR when desired and returned to the irrigation distribution system. A new pump station and associated pipeline will be required adjacent to the irrigated area to pump the water back to HPR. The remaining five fields will be irrigated with a central pivot irrigation system that will allow the use of both fresh and recycled water.

Recycled water and freshwater will be dedicated to maintain the fields during non-emergency periods. A levee will surround the containment fields to allow for its deliberate flooding. The volume of recycled water that could be temporarily contained in the fields during an emergency event will depend on the containment area and the height of the levee. A 50-acre field with a one-foot levee could contain over 16 million gallons, or slightly less than four days of discharge from the treatment plant at current flows. The other fields irrigated with central pivot systems will regulate the volume of water applied in accordance with the nutrient management plan. See sub-section 2.12.1 for project-level details.

The irrigation area will consist of two separately diked containment fields, 24 and 25 acres in size, and seven fields, ranging in size from 47 to 120 acres, irrigated by central pivot irrigation systems. Management of the water will comply with the nutrient management plan generated for the Diamond Valley Ranch.

#### N.1.2 Project Component 18 - Optimize Application Rate on Existing Irrigated Lands

The following project description is on page 2-16 of section 2.6.2.

Project Component 18 comprises Master Plan Project 11 (Prepare Nutrient Management Plans). Nutrient management plans or NMPs will be developed for all portions of the project area that receive recycled water exceeding a Total Nitrogen concentration of 3 mg/L, as required by the California State Water Resources Control Board's (State Board) Recycled Water Policy that was adopted February 2009. The site-specific application rates determined in the NMPs will modify the "effluent contracts" for the contracted irrigators as well as the permits issues by the Regional Water Quality Control Board -Lahontan Region (Lahontan).

The application rate for recycled water used for irrigation on permitted lands is based on the hydraulic loading rate and nutrient needs of the combinations of soil and crop types. Optimization of the

application rate is necessary to protect groundwater and surface water resources from possible contamination by nitrogen or other nutrients present in the recycled water and to avoid generation of tailwater. Optimization ensures no losses other than those intended (that is, evapotranspiration and some percolation). The application rate is controlled by soil permeability and the nutrient requirements of the irrigated crops.

To develop a recycled water allocation system that maximizes the volume of applied recycled water and minimizes the threat to ground and surface waters, the soil and crop type in the irrigated areas will be assessed and mapped. These data will be used to develop recycled water application rates that meet crop nutrient needs as well as protect groundwater and surface water resources. The volume of recycled water that is currently applied exceeds the hydraulic loading rate of available permitted lands and results in runoff and tailwater discharges. Implementation of Project Component 18 will alter the application of recycled water on permitted lands.

#### N.1.3 Project Component 19 - Pursue the Permitting of More Land in Alpine County

The following project description is on page 2-16 of section 2.6.2

Project Component 19 comprises Master Plan Project 12 (Permitting of Recycled Water Use in Diamond Valley). The portion of the Diamond Valley Ranch that will contain the irrigation fields described under Project Component 11 above must be permitted to receive recycled water. Currently, the lands are irrigated utilizing the freshwater rights diverted from the West Fork of the Carson River and Indian Creek.

The ability to use recycled water as a source of irrigation water is an asset to agricultural production. Currently, 1,883 acres are permitted to receive recycled water in Alpine County. Of the 1,833 permitted acres, roughly 75 percent (1,411 acres) use recycled water for irrigation. This acreage is not adequate to receive the 5,200 AF/yr of recycled water currently generated, and less than the 6,400 AF/yr estimated to be generated by the year 2020. Development or other changes to non-agricultural land use in areas currently receiving recycled water will likely result in the loss of permitted acreage. Additional lands will need to be permitted for the application of recycled water if other alternative recycled water uses are not implemented.

### N.2 Project-Level (Current Projects) Descriptions

Master Plan Projects 1, 2, 11 and 12 are prioritized for expedited implementation (within the next 5-8 years) to resolve the issues of inadequacy with the On-Farm emergency disposal system (page 13-100, Stantec 2008). Project Components 11, 18 and 19 comprise Master Plan projects 1, 2, 11 and 12, the current projects that require project-level analysis in accordance with CEQA guidelines. The following project-level descriptions are from pages 2-41 through 2-45 of section 2.12.

#### N.2.1 Master Plan Project 1 – Recycled Water Irrigation Fields on Diamond Valley Ranch and Master Plan Project 2 – HPR Bypass System Pipelines and Ditches

#### N.2.1.1 Master Plan Project 1

Project Components 11 and 19 will be implemented as part of Master Plan Project 1, Recycled Water Irrigation Fields on Diamond Valley Ranch. Project Component 11 constructs irrigation fields with pumping back to Harvey Place Reservoir and Project Component 19 pursues the permitting of more land in Alpine County to receive recycled water. With completion of Project 1, an additional 904 acres of direct land application of recycled water becomes possible. The irrigation fields will normally be used for

surface and aerial irrigation of alfalfa or native pasture grasses as identified in the Diamond Valley Ranch Nutrient Management Plan (Appendix F). Figure 2-6 shows the location of the irrigation fields within the project area. A total of seven irrigation fields are proposed. Five of the seven irrigation fields, approximately 393 acres, will be central pivot irrigation fields. Two other two fields will serve 49 acres of temporary containment area. The remaining approximately 511 acres of water-righted lands will continue to be flood irrigated with fresh water.

An evaluation of the existing recycled water emergency containment facility (On-Farm) determined the need for a new facility that can be utilized in a variety of scenarios and hydrologic conditions. Two of the seven irrigation fields will also function as temporary containment fields or basins. For temporary containment, the impoundment of water could be between one to 60 days in duration. Based on the District's last 20 years of application history, the use of these containment basins would not have been necessary under normal operations, but the January 1997 flood event presented a volume of recycled water that could have resulted in non-compliance with Lahontan water discharge requirements (WDRs) because of inadequate system capacities. Construction of temporary containment will provide the District flexibility to better respond to future temporary containment situations, which generally will be a flood event.

Five of the seven fields will be irrigated with central pivot irrigation and will vary in size from 47 acres to 120 acres. Each central pivot irrigation field is composed of a central hub where the pivot assembly is connected to the irrigation spans. The spans are composed of several segments of pipe joined together and supported by trusses mounted on wheeled towers with sprinklers positioned along its length. The water source is connected to the central hub of the irrigation system thereby allowing the spans to rotate around the pivot point administering the water for irrigation. Different nozzles are available for the controlled release of the water application/irrigation. Nozzle types vary from aerial spray, rotary sprinkler head to drip systems. Initially, the freshwater irrigation will be used to irrigate the existing native grasses present within the Diamond Valley Ranch.

In order to irrigate the central pivot irrigation fields with freshwater, a new pipeline will be required to be installed from the existing freshwater pipeline outfall from ICR located below the Harvey Place Dam, or from the existing pond located behind and west of the ranch house. The pipeline will then be connected to the five central pivot hubs as shown on Figure 2-6. Irrigation of the fields with recycled water will require additional pipeline connections from the proposed HPR bypass pipeline as described below. Alfalfa production will be introduced during recycled water application within the central pivot irrigation fields (see Phase 1B below). Use of the central pivot system on the five irrigation fields will allow for better recovery and management of tailwater. Figure 2-7 depicts the slight relocation and reconfiguration of fields 6 and 7. The fields were reconfigured to protect a cultural resource site identified during site-specific cultural resource investigations.

Two of the seven irrigation fields will be surface irrigated with fresh and recycled waters and will also serve as temporary containment fields for recycled water during times of emergency. Field 1 is 24 acres and Field 2 is 25 acres in size. The fields will be developed on the Diamond Valley Ranch adjacent to Diamond Valley Road. The irrigation fields will slope less than 2 percent% to accommodate surface irrigation practices and to-will have a common sump pump to facilitate draining and water management. The irrigation area and locations are illustrated in Figure 2-5. The irrigation area consists of two separately diked fields. The fields will be surrounded by a six-foot high berm and diked. Field One will impound 74.6 AF, while Field Two will impound 79.3 AF. Pasture grass or alfalfa will be grown to uptake and metabolize nutrients, salts and water.

Recycled and freshwater water will be dedicated to maintaining the fields during non-emergency periods. The six foot high berm will surround the irrigated area to allow for surface irrigation. The volume of recycled water that can be temporarily contained depends on the containment area and the height of the levee. A 49-acre field with a six-foot levee can contain close to 96 million gallons or 24 days of discharge from the WWTP at current flows.

Project 1 allows for surface and aerial irrigation that can function in all seasons. Initially the fields will be irrigated with existing freshwater rights diverted from the West Fork of the Carson River and Indian Creek. Recycled water will be used for irrigation as demand for application increases. In practice, Fields 1 and 2 will only hold recycled water in times of temporary containment. During normal operations, the fields provides alternative uses such as alfalfa and pasture grass production. To move temporarily contained water from Fields 1 and 2 to the outlet of HPR for redistribution, a pump-back system is necessary (see Master Plan Project 2).

A Nutrient Management Plan (NMP – Appendix F) was prepared for the Diamond Valley Ranch. The recommended crop types are alfalfa and pasture grass and the application rates are 5.99 and 3.03 AF/yr of surface irrigation, respectively. Areas disturbed by trenching will be revegetated as outlined in standard practice SP-8, Repair Road Damage and Revegetate Temporarily Disturbed Sites.

The land is currently not permitted to receive recycled water. Recycled water direct land application permits from Lahontan are required prior to construction of the irrigation fields. Restrictions on the duration of storage may be imposed for groundwater protection, which will affect the required pumping capacity of the irrigation fields pump back station. Irrigation areas will require signage and public notification of the application of recycled water.

Implementation of Project 1 will enable the District to address the need for adequate temporary containment facilities for recycled water and increased operational flexibility for recycled water systems.

Figure N.1 (same as Figure 2.7) Recycled Water Irrigation Fields Study Area (11X17)

South Tahoe Public Utility District Recycled Water Facilities Master Plan This page intentionally left blank.

#### N.2.1.2 Master Plan Project 2

Master Plan Project 2, HPR Bypass System Pipelines and Ditches, will also implement Project Component 11. This part of Project Component 11 will construct pipelines for pumping impounded recycled water back to HPR. The District will construct irrigation fields (Fields 1 and 2 discussed above) so that the temporarily contained recycled water can be pumped back to HPR or the Diamond Ditch and returned to the irrigation distribution system. A new pump station and associated pipeline will be constructed adjacent to the irrigated area in order to pump the water back to HPR.

One of the concerns of the existing recycled water C-line conveyance system is the inability to bypass recycled flows around HPR for maintenance or temporary containment purposes. The new pipelines for the HPR Bypass System include: the HPR Bypass Pipeline, the District Pasture Pipeline, and the HPR/ Irrigation Field Connector Pipeline. The HPR Bypass Pipeline will connect to C-Line near the District Pasture at the Millich Ditch crossing and extend to the Irrigation Fields. The HPR Bypass Pipeline will connect to the HPR through the Irrigation Field Connector pipeline to allow for a secondary method of routing flows to HPR or Diamond Ditch.

The general positioning of the three feasible pipeline alignments A, B and C are illustrated in Figure 2-5. Temporary pumps will be installed at the eastern end of the fields. The pipeline installed under alignments A, B, or C will be a pressure-rated, gravity flow, 18-inch diameter pipe to match the existing C-Line and will be buried to a depth of at least 3.5 feet. Pipeline alignment A is 10,180 linear feet and will required 5,279 cubic yards (yds<sup>3)</sup> of excavation. Alignment B is 9,050 linear feet and will require 4,693 yds<sup>3</sup> of excavation. Alignment C is 9,645 linear feet and will require 5,001 yds<sup>3</sup> of excavation. The temporary containment fields will be surrounded by a six-foot high berm and diked.

The HPR/Irrigation Fields Connector pipeline is approximately 2,100 feet in length and is planned as 24inch diameter bidirectional pipeline to connect to the Diamond Valley Ranch Pipeline, an existing 24-inch steel pipeline that provides a method of directing flow from the HPR outlet facility to Diamond Ditch. From the outlet facility recycled water and freshwater can be directed to the Diamond Ditch and to Indian Creek, respectively. The HPR Bypass Pipeline working in conjunction with the HPR/Irrigation Fields Connector, the existing Diamond Valley Ranch Pipeline, and the HPR Outlet Facility will allow recycled water flow to completely bypass HPR and flow into Diamond Ditch. Through implementation of Master Plan Project 2, the District will provide for adequate temporary containment needs and sufficient operational control of the distribution systems.

#### N.2.1.3 Project Phasing

Master Plan Projects 1 and 2 will be implemented in three phases: Phase 1A, Phase 1B, and Phase 2. Phase 1A (Master Plan Project 1) will i install the five central pivot irrigation sites, along with the freshwater pipeline connections. Phase 1B (Master Plan Project 1) will install the HPR bypass pipeline and connect pipelines to the central pivot irrigation sites to allow for application of recycled water. Phase 2 (remaining portions of Master Plan Projects 1 and 2) will construct the two i temporary containment fields (Field 1 and Field 2) and connect the pipeline to the HPR bypass pipeline to allow for pumping back to HPR.

#### N.2.2 Master Plan Project 11 – Prepare Nutrient Management Plans

Master Plan Project 11 will implement nutrient management plans that will be developed for all portions of the project area receiving recycled water exceeding Total Nitrogen concentrations of 3 mg/L, as required by the California State Water Resources Control Board's (State Board) Recycled Water Policy (adopted February 2009). Master Plan Project 11 is accomplished through implementation of Project Component 18, Optimize Application Rate on Existing Irrigated Lands. NMPs will be developed in accordance with requirements set forth in the State of California Recycled Water Policy. The NMP

recycled water irrigation application rate information will be used to modify the "effluent contract" for each contract irrigator and in turn the Regional Water Quality Control Board - Lahontan Region (Lahontan) permits. The application rate for recycled water used for irrigation on existing permitted lands is based on topography, hydraulic loading rate and nutrient needs of the various combinations of soil and crop types. Optimization of the application rate is required to protect groundwater and surface water resources in the region from possible contamination by nitrogen or other nutrients and salts present in the recycled water. Optimization of application rates also helps avoid generation of tailwater. This optimization ensures there are no loses other than those intended (that is, evapotranspiration and some percolation). The application rate is controlled by soil permeability and the nutrient requirements of the irrigated crops.

To develop a recycled water allocation system that will both maximize the volume of applied recycled water and minimize the threat to groundwater and surface water, the soil and crop types in the irrigated areas must be assessed and mapped. These data are used to develop recycled water application rates that meet crop nutrient needs and protect groundwater and surface water resources. The application rates are detailed in Appendix K of the Master Plan. The volume of recycled water that is currently applied exceeds the hydraulic loading rate of available permitted lands resulting in runoff and tailwater discharges. Implementation of this component will likely result in a reduction in the volume of recycled water that is applied. A groundwater monitoring system to detect nitrogen in the shallow groundwater during temporary containment may be necessary. Implementation of Master Plan Project 11 allows the District to address the potential for nitrate accumulation in groundwater through regulating recycled water application rates.

Wood Rodgers completed the Draft NMP for the Diamond Valley Ranch portion of the project area in March 2009. The purpose of the Draft NMP is to determined the best combination of crop and irrigation methods to maximize recycled water reuse and nutrient uptake while also protecting groundwater and surface water resources. Wood Rodgers initial calculations consider crop consumptive use or irrigation demand, crop capacity for nitrogen uptake and soil permeability to determine the maximum volume of recycled water that can be applied within the Diamond Valley Ranch. The results of the analyses determined that growing alfalfa with surface (flood/furrow) irrigation will maximize recycled water reuse and nutrient uptake. Growing alfalfa with spray irrigation methods will yield a similar application rate with reduced risk of tailwater.

The technical report addressing Assimilative Capacity of the Diamond Valley Ranch is found in Appendix 4 of the NMP. The complete NMP is included in this EIR as Appendix F. Lahontan defines assimilative capacity as "the ability of a [ground] water body to receive and accommodate natural and anthropogenic sources (non-point and point sources), while maintaining water quality standards that are protective of beneficial uses of the water resource" (Lahontan Assimilative Staff Report).

The initially calculated maximum recycled water application rate is 71.89 in/yr, which equates to 5.99 AF/yr for 904 irrigable acres or a total flow of 1,765 Mgal/year or 4.8 MGD. This maximum allowable application rate exceeds the current average discharge from the Districts WWTP. The crop requirements as well as the District's objective to maximize recycled water for irrigation purposes can be met given the site-conditions on the Diamond Valley Ranch portion of the project area. Tailwater management controls are necessary and are outlined in Section 7.0 of the Diamond Valley Ranch NMP and included as part of SP-33, Surface and Ground Water Protection Program.

Based on the assumption that the District intends to reuse the entire annual volume of recycled water, the recommended application rate calculated for growing alfalfa with surface irrigation is 66.80 in/yr or 5.57 AF/yr for the 904 irrigable acres. If the District chooses to be more conservative, aerial irrigation methods for growing alfalfa with spray irrigation methods will be a maximum application rate of 66.75 in/yr or 5.57 AF/yr with minimal resulting tailwater.

Grazing is not recommended under a recycled water regime because of nutrient inputs from manure. As stated in the Grazing Options Tech Memo of the NMP: "Under a treated effluent irrigation regime, irrigating fifteen days per month for eight months, grass hay pasture, with no livestock grazing the [Diamond Valley Ranch] results in an estimated deficit of all major nutrients Nitrogen, Phosphorus and Potassium" (page 6).

## N.2.3 Master Plan Project 12 – Permitting for Recycled Water Use in Diamond Valley

Master Plan Project 12 requires the implementation of Project Component 19, the permitting of more land in Alpine County, mainly for use of recycled water in the Diamond Valley. The Irrigation Fields described under Master Plan Project 1 must be permitted to receive recycled water both as irrigation application and as recycled water temporary containment. Implementation of Master Plan Project 12 allows the District to ensure adequate land for future recycled water application even if residential development continues to encroach and if application contracts expire.

The ability to use recycled water as a source of irrigation water is an asset to any production system. Currently, 1,883 acres are permitted to receive recycled water in Alpine County. Of the 1,833 permitted acres, roughly 75 percent (1,411 acres) use recycled water for irrigation. This amount of acreage is not adequate to receive the 5,200 AF/yr of recycled water that is currently generated, much less the 6,498 AF/ yr estimated to be generated by the year 2028. Development in areas currently receiving recycled water will likely result in the loss of permitted acreage. Additional lands will need to be permitted for the application of recycled water if other alternative recycled water uses are not implemented.

### N.3 Summary of Project-Level Analysis

The following Significant Mitigable impacts and Significant Unavoidable impacts that apply to Project Components 11, 18 and 19 are extracted from the overall analysis completed in environmental resource chapters 4 through 18 in sub-section Environmental Consequences (Impacts) and Recommended Mitigation. Determinations of No Impact or Less than significant Impact are not presented.

## Impact: GEO-2. Will Project Components be subject to ground rupture due to location near a surface trace of an active fault? (Page 6-15 of section 6.6.2)

#### Analysis: Significant Impact; Components 11

Surface fault rupture associated with seismic activity will result in pipeline damage and/ or rupture. Pipe rupture will result in release of recycled water and will cause substantial erosion at the discharge point. Damage to pipelines occurs throughout eastern California and western Nevada in the event of a large earthquake. The existing system as well as components proposed by the Project will be vulnerable to damage. Damage to pipelines is an unavoidable consequence of construction and operation of a recycled water system in a seismically active area.

Temporary containment Component 11 is located on three Alquist-Priolo earthquake fault zones, and crosses the end of a fourth. Surface fault rupture associated with seismic activity could cause a breach in the substrate of the irrigation field or overtopping of the embankment. The impoundments will be designed with additional freeboard to reduce the risk of overtopping in the event of a seismic event. As proposed and illustrated in Figure 2-5, Field 1 and Field 2 will be sized at 24 and 25 acres, respectively. The fields will be surrounded by a six-foot high berm and diked. Implementation of Component 11 is subject to standard practice SP-21, Temporary Containment and Impoundment Siting and Design. Impoundments larger than 50 acre-feet or with embankments more than 25

feet tall are required to meet design requirements of the California Division of Safety of Dams. District temporary containment basins will be sized much smaller than these dimensions.

An off-site alternative for the temporary containment basins and fields was considered but rejected from further analysis. The District considered off-site temporary containment areas during the Master Plan development process and eliminated the Gansberg property, Ace Hereford property and Swake property from further consideration. Criteria for the temporary containment site include:

- Proximity to Recycled Water Inflow Pipeline to Reservoir;
- Ability to receive waters from Harvey Place Reservoir; and
- Suitability of Soils and terrain.

The analysis of off-site alternatives prepared by Matthew Setty in a series of memorandums dated March 2001 is summarized in Chapter 2, Section 2.7.

The potential for damage to facilities is reduced through implementation of SP-17, Pipeline Design Features in Active Fault Zones. The District will design pipelines crossing active faults with isolation valves. Automatic valves will be used whenever feasible. Pipelines will be sited outside of fault zones whenever possible. During final design, engineers will implement standard engineering design features to reduce the effects of a potential pipeline break, but cannot prevent a pipe rupture in the event of a seismic event. The impact remains significant.

Mitigation: No additional mitigation is possible. Component 11

After

Mitigation: Significant Impact; Component 11

No mitigation measures are available for recommendation above and beyond designing and engineering facilities to withstand ground rupture within or in the vicinity of the project area. The situation remains that the faults that run through the project area are considered active and pose the potential to cause ground rupture.

#### Impact: GW-1. Will the Project Components degrade groundwater quality in the Carson, Wade and Diamond Valleys? (Page 7-19 of section 7.6.2)

Analysis: Significant Impact; Component 11

Degradation of groundwater quality will occur if the migration of recycled water into groundwater results from operations of the irrigation and temporary containment fields of Component 11. Implementation of Component 11 will increase access to and application of recycled water and/or irrigation of additional lands with recycled water that contains nutrients in concentrations above those measured in local groundwater sources. If application rates exceed site-specific hydraulic loading levels, recycled water will interact with shallow groundwater sources and groundwater quality could be degraded.

Through implementation of Component 11, Construct irrigation fields with pumping back to HPR, an additional 904 acres of direct land application of recycled water will be possible. The irrigation fields will normally be used for surface and aerial irrigation of alfalfa or native pasture grasses, the crops recommended in the Diamond Valley NMP

(see Appendix F). Seven irrigation fields are proposed and are illustrated in Figure 2-6. Five of the seven fields will be central pivot irrigation fields (approximately 334 acres) and two of the fields will be for temporary containment of recycled water (49 acres). The remaining water righted lands will continue to be flood irrigated with freshwater. Application of freshwater is discussed in the analysis for NP-1 and will not result in degradation to groundwater quality.

Component 11 will first (project Phase 1A) construct five irrigation fields, ranging in size from 47 to 120 acres and install central pivot spray systems for irrigation with freshwater. The HPR by-pass system and connecting pipelines to the central pivot irrigation sites will be installed in Phase 1B, which will allow for irrigation with recycled water. Over time the irrigation system will apply recycled water or a blend of fresh and recycled water. Central pivot systems allow for optimized water application and metering of application rates.

The soils in the project area are reported (Wood Rodgers 2008) to be loamy sand, sandy loam and sand, in order of dominance. These soil textures are very conducive to sprinkler or flood/furrow irrigation practices. There was one occurrence of clay loam, which is a layer or accumulation of clay; the clay content is not high enough to meet the criteria as a restrictive layer for infiltration of irrigation water. The misapplication of recycled water will result in the migration of recycled water into shallow groundwater sources and the degradation of groundwater quality.

The Diamond Valley Ranch is currently grazed in the spring through the early fall by approximately 1,000 head of cattle. The Grazing Options Technical Memorandum attached in Appendix F as part of the Diamond Valley Ranch NMP states that the continuation of grazing after the transition to a recycled water irrigation regime will result in a small excess of Nitrogen (630 lb/yr) when considering Nitrogen available in recycled water and manure input measured against crop uptake. The modeled scenario of recycled water irrigation measures the relative impacts of flood irrigation methods for pasture grass and irrigating 15 days per month for eight months of the year to determine relative impacts. Nitrogen loading is notably small considering that current District effluent concentrations can deliver close to 661 pounds of Nitrogen a day. The impact is significant over time, and could contribute to cumulative impacts to groundwater quality.

Phase 2 will construct Field 1 (24 acres) and Field 2 (25 acres) with six foot high berms to allow for the temporary containment of up to 96 million gallons or 24 days of discharge from the WWTP during times of emergency, typically flooding events similar to the January 1997 precipitation event. The HPR bypass system will allow for the pumping of temporarily contained waters back to HPR or to the Diamond Ditch during the period of April 1 through October 15. Increased inputs of recycled water into groundwater could result from the unlined containment fields depending on the timing and duration of containment, altering groundwater levels and potentially increasing Nitrate-Nitrogen concentrations in groundwater if mixing occurs in the unsaturated zone of shallow groundwater sources. Containment of recycled water could be between one and 60 days in duration under a worst-case scenario, according to the District. Based on the District's last 20 years of application history, the emergency use of these temporary containment fields would not have been necessary and thus the future need is inferred to be low.

Project-level investigations, as detailed in section 7.2.5, were completed in November and December of 2008. The Farr West Engineering report is attached in Appendix I-b and presents project-specific conditions and recommendations for Component 11. Water level data indicate that low to virtually impermeable material separates multiple

permeable units. The study concludes that the northern portion of Diamond Valley Ranch could receive recycled water for irrigation and temporary containment with low infiltration rates into the upper most portion of the shallow alluvial zone because of the generally fine-grained and poorly sorted material. Movement of recycled water from the shallow alluvial zone to the lower semi-confined and confined alluvial zones are expected to be minimal because of the interbedded alluvial and morainal deposits that form confining layers that will retard infiltration.

However, transmissive losses from the temporary containment fields could occur under the extreme conditions that would warrant the use of the temporary containment fields, and significant impacts to groundwater quality could result if containment duration is prolonged The combination of early spring soil conditions and an emergency event occurring prior to April 1st, the date on which recycled water is permitted to be released from HPR, represents the worst-case scenario for temporary containment. To reduce potential impacts to groundwater resources to a level of less than significant, determination of the maximum duration of containment that site conditions can support is necessary.

Mitigation: SP-33. Surface and Ground Water Protection Plan

**GW-1A.** Remove Cattle Grazing from Portions of the Diamond Valley Ranch Irrigated with Recycled Water

GW-1B. Do Not Exceed the Maximum Duration of Temporary Containment (100 Days)

After

Mitigation: Less than Significant Impact; Component 11

Implementation of standard practice SP-33 and recommended mitigation measures GW-1A and GW-1B will reduce potential impacts to groundwater quality from Component 11 to a level of less than significant.

The District will follow the Surface and Ground Water Protection Plan (SP-33) for continued characterization of groundwater quality for the project area. Should groundwater Nitrate-Nitrogen concentrations approach 7 mg/L, the proposed action concentration level, the District will amend or suspend irrigation with recycled water as appropriate to reduce impacts to groundwater.

In order to determine the hydraulic loading based on nitrogen for the Diamond Valley Ranch NMP,, Wood Rodgers consulted "WTS-1B: General Criteria for Preparing an Effluent Management Plan," prepared by the Nevada Department of Environmental Protection (NDEP). Wood Rodgers set a conservative "red-flag" threshold level of 7 mg/ L for  $C_P$ , as is common practice in developing a Nevada Effluent Management Plan (EMP). This was done to insure that the receiving groundwater resource will not be degraded to a point where it is no longer useable (please refer to the Appendix F, Assimilation Capacity-Technical Report 4). The District understands that Lahontan and the State Board can impose a more stringent trigger value if an additional factor of safety is desired.

Recommended mitigation measure GW-1A requires an amendment to the grazing regime and/or manure management to reduce Nitrogen loading if recycled water is used for irrigation. In lieu of amending the grazing timeframes, crop type, and manure

management necessary for a nutrient neutral grazing regime, the District will commit to removing cattle from portions of the Diamond Valley Ranch when irrigating with recycled water. The removal of cattle during a recycled water irrigation regime is determined to result in deficiencies in the "whole ranch nutrient balance" for Phosphorus, Potassium, and Nitrogen, which assures the protection of groundwater resources. Balancing Nitrogen inputs with crop uptake, manure inputs will reduce impacts to groundwater quality to a level of less than significant.

Under recommended mitigation measure GW-1B, 100 days is the maximum duration of impoundment of recycled waters that will meet the needs of temporary containment situations without creating impacts to groundwater quality. The investigation of the northern Diamond Valley Ranch portion of the project area, which is the proposed location for irrigation fields and temporary containment suggests that shallow confined layers will retard infiltration from the uppermost portion of the water tables into lower water bearing zones (Farr West Engineering 2009). The study concludes that the northern portion of Diamond Valley Ranch could receive recycled water for irrigation and temporary containment with low infiltration rates into the upper most portion of the shallow alluvial zone because of the generally fine-grained poorly sorted material.

A containment duration of 100 days will meet the needs of the District to temporarily contain up to 96 million gallons of recycled water exported from the WWTP during an emergency situation while protecting groundwater quality of the water bearing unit. The District worked with Farr West Engineering to predict concentrations of mixed waters during a worst case scenario of 100 days of containment during saturated soil conditions, which is typically late May through late July.

A standard one dimensional mass flux equation was used to predict potential groundwater impacts from temporary containment of recycled water of a concentration of 1.53 mg/L of Nitrate-Nitrogen, which is the median concentration measured in the recycled water exported from the WWTP over the previous 20 months. The scenario predicts a resultant Nitrate-Nitrogen concentration of 2.16 mg/L, should mixing occur. This concentration is well below the proposed action level of 7.0 mg/L and the State of California maximum drinking water level of 10.0 mg/L.

An adequate depth to groundwater separating the unlined bottoms of the containment fields from the unsaturated zone of the water table will assure that groundwater quality is protected during times of temporary containment and that potential impacts are reduced to a level of less than significant. This depth of separation and minimized mixing of recycled waters with groundwater will be maintained by restricting the duration of containment to not more than 100 days. Continued groundwater monitoring (SP-33) is necessary to assure groundwater protections and that the District can respond promptly to changes in site conditions.

Analysis: Significant Impact; Component 19 (Page 7-25 of section 7.6.2)

A number of the Project Components could result in migration of recycled water into groundwater, which could adversely affect groundwater quality. Implementation of Project Component 19 will increase access to and application of recycled water and/or irrigation of additional lands with recycled water that contains nutrients in concentrations above those measured in local groundwater sources. If application rates exceed site-specific hydraulic loading levels, recycled water will interact with shallow groundwater sources and groundwater quality could be degraded. Application component 19 will construct infrastructure for irrigation and application of recycled waters.

#### SP-33. Surface and Ground Water Protection Plan

## **GW-1A.** Remove Cattle Grazing from Portions of the Diamond Valley Ranch Irrigated with Recycled Water

#### After

Mitigation: Less than Significant Impact; Component 19

Component 19 will impact the Diamond Valley Ranch portion of the project area through application of recycled water. The District worked with Wood Rodgers, Inc. to develop a NMP specific to site conditions of the Diamond Valley Ranch and in fulfillment of the State Board's forthcoming Recycled Water Policy. Potential impacts to groundwater quality in the Diamond Valley will reduced to a level of less than significant through adherence to the application rates and volumes calculated for these sites along with implementation of surface and groundwater protection measures and monitoring outlined in the NMP and SP-33. Component 19 pursues permitting of more land in Alpine County. Maximum application rates and volumes recommended for this Project Component is discussed below.

The Diamond Valley Ranch NMP is developed primarily for use by the re-user and secondarily as a reporting mechanism for Lahontan. The purpose of the NMP is to provide guidance for irrigating with recycled water as listed:

- Provide a description of the recycled water delivery system and ancillary system components to inform responsible personnel of the system operation and capabilities;
- Identify responsibilities of the permittee/operator on the operation, maintenance and management of the recycled water reuse on the permitted site;
- Instruct system operators in the purpose and intended operation of components within the irrigation system under normal operating conditions and during emergency conditions, including procedures for emergency response and notification; and
- Annual monitoring and reporting requirements.

Wood Rodgers determined the area of potentially irrigable lands using recycled water on Diamond Valley Ranch as 904 acres. The irrigable acres are delineated in Figure 2 of Appendix F. Areas that are currently irrigated with fresh water and/or have been irrigated historically were considered. Protection of surface water and groundwater quality are incorporated through 25-foot setbacks from the District property lines along Diamond Valley Road, from the center line of irrigation ditches, and from the edge of stream courses. Areas of high groundwater are identified based upon field visits, aerial photography, the results of August 2008 soil sampling and the District's groundwater monitoring data.

The maximum recycled water application rate is calculated at 71.89 inches per year (in/ yr), which equates to 5.99 AF/yr for the 904 irrigable acres or a total flow of 1,765 million gallons per year (Mgal/yr) or 4.8 MGD. As stated in the Executive Summary of the Diamond Valley Ranch NMP (Appendix F, p.i), this is the maximum allowable application rate that will meet the crop requirements for alfalfa as well as the District's objective to use the maximum recycled water for irrigation purposes. This application rate currently exceeds the District's average yearly daily flow of 4.0 MGD or 1460 Mgal/ yr, which equates 4.95 acre-feet for irrigation each year with no net annual storage in HPR. This average yearly daily flow is reported to Lahontan in quarterly monitoring and

annual monitoring reports. This total water volume is then used as the starting point to calculate the total available amount of recycled water that can be applied each month and to develop the Nitrogen balance for maximum assimilative capacity and uptake.

The recommended application rate calculated for growing alfalfa (recommended crop type) with surface irrigation is 66.80 in/yr or 5.99 acre-feet/acre for the 904 irrigable acres. This application rate is very close to the maximum allowable application rate for growing alfalfa with spray irrigation. To be on the conservative side, the District can select an aerial irrigation method for growing alfalfa with spray irrigation, with a maximum application rate of 66.75 in/yr or 5.57 acre-feet/acre with minimal resulting tailwater (reduced surface water impacts as discussed in Chapter 8. Chapter 3.0 of the Diamond Valley Ranch NMP, Recycled Water Irrigation Planning, presents the foundation for evaluating the hydraulic loading levels.

Currently the Diamond Valley Ranch is grazed from late spring through early fall by approximately 1000 head of cattle. Livestock grazing removes nutrient from the project area through harvesting of crop while also providing nutrient input in the form of manure to the system. As stated in the NMP, the level of grazing that is occurring is moderate, dispersed and managed based on available feed. No one portion of the Diamond Valley Ranch study area (as analyzed in the NMP) will be impacted by the production of manure and associated input of nutrients under a freshwater regime. Under a recycled water irrigation regime a small excess of Nitrogen will become available. As discussed above for the analysis of component 11, to continue cattle grazing in the Diamond Valley Ranch under a recycled water irrigation regime, the carrying capacity of the crop must be determined and livestock use be limited to a moderate level on a rotation system (recommended mitigation measure GW-1A)

To reduce potential impacts to groundwater to a level of less than significant, under recommended mitigation measure GW-1A, the District will discontinue cattle grazing under a recycled water irrigation regime. The removal of cattle on the portions of the project area that are irrigated with recycled water will result in a deficit for Phosphorus, Nitrogen and Potassium. The calculations for the "whole ranch nutrient balance" under a recycled water irrigation regime including and excluding inputs from manure are detailed in Grazing Options tech Memo of Appendix F.

The monitoring program implemented under standard practice SP-33 will offer concrete responses when baseline nutrient and salt concentrations from groundwater monitoring wells show degradation of groundwater quality attributable to the recycled water program. Chapter 8.0 of the Diamond Valley NMP outlines monitoring and reporting requirements, including: recycled water volumes; recycled water quality; groundwater quality; Nitrogen balances; standard reporting procedures; emergency reporting; monitoring wells; recycled water sampling; flow monitoring; soils; and vegetation. The plan includes measures to curtail recycled water flows onto the project area either temporarily or permanently, and reduce the impacts to groundwater quality from recycled water application to a less than significant level.

# Impact: BIO-1. Will the Project Components cause loss of individuals or occupied habitat of endangered, threatened, or rare fish, wildlife or plant species directly or indirectly? (Page 11-37 of section 11.6.2)

Analysis: Significant Impact; Components 11, 19

Construction of facilities in native rangeland could affect species of concern, including pygmy rabbit, northern sagebrush lizard, Carson Valley wood nymph, Carson Valley

sandhill skipper, Webber's ivesia, and three-bracted onion. The following components have the potential for significant effects on species of concern.

Component 11 - Construct Irrigation Fields with Pumping Back to HPR, will result in conversion of rangeland and installation of two temporary containment basins on the Diamond Valley Ranch. Suitable habitat for pygmy rabbits exists in the area of the irrigation fields as well as the alternative HPR bypass pipelines. These areas were surveyed to protocol in January of 2009. No evidence of pygmy rabbits was located during the survey. The area was subsequently surveyed on May 29 for the presence of migratory bird nests and raptor nests. No nesting birds were located within the project area. No other suitable habitat for sensitive species exists in the proposed location of the irrigation fields, temporary containment basins or alternative bypass pipeline alignments.

Component 19 - Pursue Permitting of More Land in Alpine County, may result in conversion of existing pastureland or native rangeland to irrigated pasture which may cause loss of individuals or occupied habitat of sensitive species. Construction of irrigated pasture may create new habitat for sensitive species.

#### Mitigation: BIO-1. Conduct Biological Resource Assessments

#### SP-25. Sensitive Resource Program

After

Mitigation: Less than Significant Impact; Components 11, 19

The proposed mitigation will allow the District to avoid or protect biological resources, it cannot be anticipated that the Sensitive Resource Program will allow for full mitigation of impacts that have yet to be determined as the details of the components have not been finalized. The District will compensate, in kind, for disturbance or alteration of habitat that may occur as a result of project implementation. Following implementation of the Standard Practices and recommended mitigation measure BIO-1, it is unable to be determined if the impact will be reduced to a level of less than significant. This impact is considered less than significant after mitigation.

## Impact: BIO-2. Will the Project Components cause loss of individuals of CNPS List 2, 3, or 4 plant species? (Page 11-41 of section 11.6.2)

Analysis: Significant Impact; Components 11, 19

A search of the CNDDB and the CNPS databases found no records for CNPS List 2, 3, or 4 plant species within the project area. Aerial photographs of the project vicinity indicate the presence of native rangeland that could contain CNPS List 2, 3, or 4 plant species, including rocky or clayey openings in shrub land and woodland, where CNPS List 2, 3, or 4 plant species may occur. Floristic surveys have not been performed for the entirety of the project area and it is necessary to develop a Sensitive Plant Protection Program for potentially significant impacts to BLM Sensitive, CNPS and Nevada Natural Heritage Program Special Status Plant Species.

#### Mitigation: SP-26. Sensitive Plant Protection Program

After

Mitigation: Less than Significant Impact; Components 11, 19

The standard practice will require the avoidance or protection of listed native plant species. When needed, mitigation will allow the Project to compensate, in kind, for loss of individuals of listed species. Many of the projects outlined in the Master Plan may be implemented in the future. Following implementation of the Sensitive Plant Protection Program, it is unable to be determined if the impact will be reduced to a level of less than significant. This impact is considered less than significant after mitigation.

## Impact: BIO-3. Will the Project Components cause loss of active raptor nests, migratory bird nests, or wildlife nursery sites? (Page 11-42 of section 11.6.2)

Analysis: Significant Impact; Components 11,19

The following project components could have adverse effects on nests or nursery sites.

Component 11 - Construct Irrigation Fields with Pumping Back to HPR, will result in conversion of pastureland, the installation of two temporary containment basins and installation of the bypass pipeline from the C-line to the basins. Suitable habitat for pygmy rabbits exists in the area, which was surveyed to protocol in January of 2009. No evidence of pygmy rabbits was located during the survey (HBA 2009). The area was subsequently surveyed on May 29 for the presence of migratory bird nests and raptor nests. No nesting birds were located within the project area. As the last field visit was performed in the winter and spring of 2009, it cannot be determined if new nests or nursery sites that will be impacted as a result of implementation of the project, therefore SP-30 shall be implemented again to ensure no new nests are established prior to commencement of project construction.

Component 19 - Pursue Permitting of More Land in Alpine County, may result in conversion of existing pastureland or native rangeland to irrigated pasture which may cause loss of individuals or occupied habitat including nests and nurseries. See Component 11 above for results of surveys.

## Mitigation: SP-30. Pre-construction Surveys for Migratory Birds ,Nesting Raptors and Wildlife Nurseries

After

Mitigation: Less than Significant Impact; Components 11, 19

The standard practice will allow the District to avoid and protect active raptor nests, migratory bird nests as well as nursery sites. Following implementation of the preconstruction surveys, it is unable to be determined if the impact will be reduced to a level of less than significant. This impact is considered less than significant after mitigation.

## Impact: BIO-4. Will the Project Components substantially block or disrupt major fish or wildlife migration or travel corridors? (Page 11-45 of section 11.6.2)

Analysis: Significant Impact; Component 11 (Pipelines)

Implementation of a portion of Component 11 could affect migration or travel corridors and will result in significant impacts:

Component 11 - The Alternative B alignment for the HPR bypass pipeline will cross the Millich Ditch in three locations, which may block the movement of strays of Lahontan cuthroat trout. The Alternative A alignment will not have any interruptions of the Millich Ditch and will not cause any interruptions to wildlife migration. The Alternative

C pipeline alignment will cross the Millich Ditch in one location. These construction activities may result in blockage of movement of strays of Lahontan cuthroat trout that may occupy the Millich Ditch. This impact is considered significant for Alternative B and C HPR bypass pipeline alignments.

#### Mitigation: BIO-4A. Fish Passage Structures and Deer Migration Corridors

#### BIO-4B. Schedule Construction to Avoid Breeding and Migrating Wildlife

After

Mitigation: Less than Significant Impact; Component 11 (Pipelines)

The proposed mitigation will require design changes to the Project to facilitate fish and deer passage and limit construction timing to periods when fish are not spawning and when deer are not migrating. These mitigation measures will reduce the Project's potential adverse effects on wildlife movements and breeding to a level of less than significant.

Analysis: Less than Significant Impact; Component 11 (Irrigation Fields)

Component 11 - Construct Irrigation Fields with Pumping Back to HPR, will result in the construction of temporary containment basins along with a pipeline from the C-line located at the junction of Diamond Valley Road and SR 89. These facilities will not result in any blockage of any stream that will contain migrating fish. The Carson River Deer Heard Management Plan (CDFG 1985) delineates migration corridors on the east side of the Carson River with some smaller corridors denoted through Wade Valley. The proposed location of the irrigation fields are outside the delineated critical winter range. When full, the irrigation fields may present a temporary interruption to the movements of the Carson River Deer Herd, but the duration of such an interruption will be short and the impact will be less than significant.

Construction of the alternative pipeline alignments for the HPR bypass pipeline will not have an impact on wildlife movements as no blockage will occur to deer migration corridors that have been mapped in the area.

- Mitigation: No mitigation is needed. Component 11 (Irrigation Fields)
- Impact: BIO-5. Will the Project Components have a substantial adverse effect on or result in the permanent loss of any riparian habitat or other sensitive natural community identified in local or regional plans, policies, regulations or by the CDFG or USFWS? (Page 11-48 of section 11.6.2)
- Analysis: Significant Impact; Component 11

Sensitive wildlife habitats are defined as habitats that provide high suitability for foraging and breeding for state and federal species of special concern and California fully protected species, and important nesting, foraging, and breeding habitat for migratory songbirds and other wildlife. Montane riparian scrub, Modoc/Great Basin riparian forest, and montane freshwater marsh are sensitive wildlife habitats identified within the project area. Section 401, Waters of the State and Section 404 Waters of the U.S. are addressed in BIO-7 below. Existing ditches all have evidence of high transmissive losses which results in seepage of both recycled (Diamond Ditch) and freshwater (Snowshoe Thompson No. 1 and Snowshoe Thompson No. 2). This seepage over time has resulted in the establishment of riparian vegetation on the banks of the earthen portions of the

ditches and downslope from the ditches. The proposed improvements to increase capacity and reduce the transmissive losses has the potential to decrease the water available to this established riparian vegetation. The existing vegetation that will be impacted will be minimal and project construction will not reduce the riparian vegetation by 10 percent or more in Alpine County, but will result in the permanent loss of riparian vegetation: this impact is considered significant. Implementation of SP-31 and SP-32 will allow the District to map, avoid and protect sensitive riparian habitat. The District will monitor the recovery and restoration of altered and/or created habitat.

Component 11 - Construct Storage Facility with Pumping Back to HPR will result in the minor removal of riparian vegetation. This vegetation is associated with the transmissive losses associated with Millich Ditch. Due to the size of the area involved with the pipeline alignments, it is not possible for project construction to permanently reduce sensitive habitat by 10 percent or more in Alpine County but will result in the permanent loss of riparian vegetation due to construction activities. Alternative bypass pipeline alignment A crosses Millich Ditch in three locations and would likely result in minor removal of individual Salix bushes. Alternative bypass pipeline alignment C would follow the dirt roadway and would cross the ditch in one location, and would not result in the removal of riparian vegetation. Alternative bypass pipeline alignment B crosses the Millich ditch (which is contained to the culvert under the roadway) and would not result in the removal of riparian vegetation. A Lake or Streambed Alteration agreement would be required to be issued by California Department of Fish and Game for Alternatives A and C due to disturbance to the Millich Ditch and associated minor removal of riparian vegetation.

Mitigation: SP-31. Pre-construction Marking and Fencing of Sensitive Native Plant Communities

SP-32. Pre-construction Marking and Fencing of Wetlands and Riparian Habitat

BIO-5A. Map Sensitive Native Plant Communities and Prepare Habitat Restoration Plan

#### **BIO-5B.** Monitor Habitat Restoration and Revegetation Sites

After

Mitigation: Less than Significant Impact; Component 11

The standard practices and proposed mitigation will allow the District to map and protect sensitive native plant communities and riparian habitat. Monitoring of habitat restoration and revegetation sites is also included to ensure the success of restoration activities. After implementation of these mitigation measures, the impact to sensitive plant communities will be less than significant.

- Impact: BIO-7. Will the Project Components have an effect on federally protected wetlands as defined by Section 404 of the CWA or waters of the U.S. through direct removal, filling, hydrological interruption, or other means? (Page 11-51 of section 11.6.2)
- Analysis: Significant Impact; Components 11, 19

Wetland delineations have not been performed on District, private or public lands in the locations of the projects and components listed in the Master Plan. Standard Practice

SP-22 Delineate Wetlands, Waters of the United States, and Riparian Habitat, SP-23 Prepare Wetland And Riparian Mitigation And Monitoring Plan, SP-26 Avoid Impacts to Wetland and Riparian Areas and, SP-21 Pre-construction Marking and Fencing of Wetlands and Riparian Habitat will be implemented prior to construction of the proposed components. Due to the fact that the delineations have yet to be performed, the exact extent of impact to wetlands cannot be determined.

Component 11 - - Construct Irrigation Fields with Pumping Back to HPR, includes three alternatives of the HPR bypass pipeline location between the junction of SR 89 and Diamond Valley road and the locations of the proposed irrigation fields.

Of the three alternative alignments shown in Figure 2-5, Alignment B crosses the Millich Ditch in three separate locations. Millich ditch conveys fresh water from the West Fork of the Carson River. No survey has been performed to determine if the areas adjacent to the ditch are considered wetlands and waters of the U.S. This ditch and associated riparian habitats that are adjacent, will likely be considered waters of the U.S. and will be directly impacted as a result of project implementation. Construction activities could result in fill entering waters of the U.S. (Millich Ditch) and impacts to the adjacent riparian areas/wetlands. This impact is considered significant.

Alternative A alignment follows the shoulder of Diamond Valley Road from the junction of SR 89/Diamond Valley Road to the location of the infiltration basins. No delineations of wetlands have been performed for the three pipeline alignments and impacts to wetlands and waters of the U.S. cannot be ascertained at this time. This impact is considered significant.

Alternative B will cross the Millich Ditch in three locations, as illustrated in Figure 2-5. Details on this crossing are no included in the project description. Construction activities could result in fill entering waters of the U.S. (Millich Ditch) and this impact is considered significant.

Alternative C follows the dirt roadway as shown in Figure 2-5 that intersects with the Millich Ditch in one location. Details on this crossing are not included in the project description. Construction activities could result in fill entering waters of the U.S. (Millich Ditch) and this impact is considered significant.

Component 19 - Pursue Permitting of More Land in Alpine County, may result in additional lands that receive recycled water for irrigation purposes. Because these lands have not been identified, they may contain waters of the U.S. and may be impacted. This impact is considered significant.

Mitigation: SP-23. Delineate Wetlands, Waters of the United States, and Riparian Habitat

- SP-24. Prepare Wetland And Riparian Mitigation And Monitoring Plan
- SP-27. Avoid Impacts to Wetland and Riparian Areas
- SP-32. Pre-construction Marking and Fencing of Wetlands and Riparian Habitat

#### **BIO-7.** Monitor Wetland And Riparian Mitigation Sites

After

#### Mitigation: Less than Significant Impact; Components 11, 19

The standard practices and recommended mitigation measure BIO-7 will allow the District to avoid or protect Wetlands and waters of the U.S.: it cannot be anticipated that these measures/practices will allow for full mitigation of impacts that have yet to be determined as the details of the components have not been finalized. Standard practices require the District to compensate, in kind, for disturbance or alteration of wetlands that may occur as a result of project/component implementation. This impact is considered less than significant after mitigation.

Analysis: Less Than Significant; Component 11 (Irrigation Fields)

Component 11 - Construct Irrigation Fields with Pumping Back to HPR, will have no impact on wetlands and waters of the U.S. As stated in the USEPA definition of Waters of the U.S. 40 CFR 230.3(s)(7) "Wetlands adjacent to waters (other than waters that are themselves wetlands) identified in paragraphs (s)(1) through (6) of this section; waste treatment systems, including treatment ponds or lagoons designed to meet the requirements of CWA are not waters of the United States." Based on this definition, creation of infiltration basins with the use of recycled water are not determined waters of the U.S. and will not have an impact. Created infiltration basins that are immediately adjacent to existing waters of the U.S. may have an impact through the interception of groundwater from the basins to waters of the U.S. (Carson River and Snowshoe Thompson Ditch #2). Inclusion of Standard Practices and compliance with the NMP prepared for the Diamond Valley (Wood Rodgers 2009) ensures less than significant impacts to groundwater from Component 11, and will not result in contaminated groundwater reaching waters of the U.S. and resultant negative effects to associated wetlands. Standard Practice SP-16, Slope Stabilization Design, will ensure the irrigation fields will be contained by berms and adequately maintained to prevent surface flow of recycled water from reaching Indian Creek, the Carson River and/or Snowshoe Thompson Ditch #2. The impact level is considered less than significant for the irrigation fields portion of Component 11.

- Mitigation: No mitigation is needed. Component 11 (Irrigation Fields)
- Impact: ARCH-1. Will the Project Components disturb known potentially eligible National or California Register properties, including archaeological, historical, architectural, and Native American/traditional heritage resources? (Page 15-18 of section 15.6.2)
- Analysis: Significant Impact; Components 11, 18, 19

Construction of the irrigation systems, irrigation fields and infiltration basins for components 11, 18 and 19 could result in impacts to cultural resources. Ground disturbance associated with the placement of the pipes, irrigation fields and infiltration basins, including the effects of heavy equipment activity and possibly ongoing maintenance activities, will result in the destruction or alteration of known prehistoric and historic archaeological sites.

Table 15-7 shows the number of prehistoric and historic archaeological sites occurring within the project area that must be avoided during construction and operation of components 1, 2, 3, 4, 5, 6, 7, 9, 10, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21 and 22.

#### Table 15-7

Number of Known Historic and Archaeological Sites Affected by Project Components

| Table 15-7               |                       |                            |                       |                                         |
|--------------------------|-----------------------|----------------------------|-----------------------|-----------------------------------------|
| Prehistoric <sup>1</sup> | Historic <sup>2</sup> | Architectural <sup>3</sup> | Prehistoric/          | Total                                   |

Notes: 1 - Prehistoric archaeological site

2 - Historic archaeological site

3 - Historic architectural site

4 - Site with both prehistoric and historic components

#### Mitigation: ARCH-1. Identification, Evaluation, and Avoidance of Cultural Resources

After

Mitigation:

on: Less than Significant Impact; Components 11, 18, 19

Implementation of the Programmatic Agreement (PA), as outlined for mitigation measure ARCH-1, Identification, Evaluation, and Avoidance of Cultural Resources, which presents measures to avoid, reduce, or mitigate impacts, requires: an evaluation of archaeological resources by a qualified archaeologist; a determination of resource significance, consultation with the Washoe Tribe, and resulting management/mitigation The treatment of cultural resources to be affected by the Project recommendations. Components will continue to be addressed under Section 106 process of the National Historic Preservation Act. The PA provides for a phased resource identification, evaluation and data recovery program. Phase I and Phase II have been completed for portions of the project area effected by Project Components 11, 18, and 19. Phase III and Phase IV of the PA will be implemented as necessary prior to and during construction of individual Project Components as determined by National Register significance. Phase III and Phase IV call for the development of a treatment plan and supervision of archaeological monitoring during construction, respectively with involvement of the Washoe Tribe.

These actions apply to all Project Components that result in a physical change to the project area to reduce the impacts to pre-historic and historic archaeological sites to a less

than significant level. For impacts identified in California, the PA will be implemented under CEQA. For impacts identified in Nevada, the PA will be implemented under Nevada State Register standards.

## Impact: ARCH-2. Will the Project Components disturb unknown archaeological resources or human remains? (Page 15-21 of section 15.6.2)

Analysis: Significant Impact; Components 11, 18, 19

There is the possibility that surface or subsurface cultural resources not identified during the review of records at the CCIC and the NSM will be encountered during construction or operation/maintenance of pipelines, irrigation systems, irrigation fields, infiltration basins and impoundments, or that there are unexpected effects on known cultural resources.

#### Mitigation: ARCH-1. Identification, Evaluation, and Avoidance of Cultural Resources; ARCH-2. Protect Undiscovered Cultural Resource Sites

After

Mitigation: Less than Significant Impact; Components 11, 18, 19

An archaeological pedestrian survey as identified in Mitigation Measure ARCH-2, Protect Undiscovered Cultural Resource Sites, as well as the preparation of the PA required for measure ARCH-1 in cooperation with the Washoe Tribe, will reduce this impact to a less than significant level.

For Project Components 11, 18 and 19, the District will retain an archaeological monitor, who meets Secretary of the Interior standards, to be present during certain phases of project construction and to conduct in-field monitoring in areas of known resources and areas of high archaeological sensitivity. If human remains are discovered, the county coroner must be notified as soon as reasonably possible (CEQA Section 15064.5) and there will be no further disturbance to the site where the remains were found. Treatment of the remains will be dependent on the views of the most-likely-descendent.

## Appendix O - Comments Received on Draft EIR

#### STATE OF CALIFORNIA -- THE RESOURCES AGENCY

Mr. Jim Hoggatt South Tahoe Public Utility District 1275 Meadow Crest Drive South Lake Tahoe, California 96150

SCH #2007042116, Notice of Preparation for the South Tahoe Public Utility Recycled Water Facilities Master Plan Draft Environmental Impact Report, January 2009 Alpine County

Dear Mr. Hoggatt:

We have reviewed the subject Notice for this project, which includes the construction of a storm water ditch at the southeast corner of Harvey Place Reservoir and the construction of a spillway channel for Indian Creek Reservoir that conveys reservoir spillage around Harvey Place Reservoir.

Indian Creek Dam, No. 1062 and Harvey Place Dam, No. 1062-3 are currently under the jurisdiction of the Division of Safety of Dams. If any alteration to the dams or their appurtenances is anticipated, an alteration application, together with plans and specifications, must be filed with the Division. All dam safety related issues must be resolved prior to approval of the application and the work must be performed under the direction of a civil engineer registered in California. Mark Schultz, our Acting Design Engineering Branch Chief, is responsible for the application process and can be reached at (916) 227-4619.

If you have any questions or need additional information, you may contact Office Engineer Mike Sutliff at (916) 227-4601 or Regional Engineer Mike Zumot at (916) 227-4631.

Sincerely,

## Michael Wagom For

RE: South Tahoe PUD Recycled Water Facility Master Plan - SCH#:2007042116

Dear Mr. Hoggatt,

The California Department of Public Health (CDPH), Environmental Review Unit (ERU) is in receipt of the Environmental Impact Report for the above project. As a responsible agency under the California Environmental Quality Act (CEQA), we appreciate the opportunity to comment.

The CDPH, Division of Drinking Water and Environmental Management is responsible for issuing water supply permits administered under the Safe Drinking Water Program. A new or amended Water Supply Permit may need to be issued for the above referenced project if it includes an increase in water supply, storage, or treatment of drinking water. These future developments may be subject to separate environmental review.

For questions or information on the Water Supply Permit application process, please contact the CDPH Sacramento District office at (916) 449-5600.

Sincerely. Bridget Binning

ARNOLD SCHWARZENEGGER, Governor DONALD KOCH, Director

August 12, 2009

**IFARNI** 

Jim Hoggatt South Tahoe Public Utility District 1275 Meadow Crest Drive South Lake Tahoe, CA 96150

Dear Mr. Hoggatt:

The Department of Fish and Game (DFG) has reviewed the draft Environmental Impact Report (DEIR) for South Lake Tahoe Public Utility District's Recycled Water Facilities Master Plan (project). The project consists of a combination of actions to dispose of increased amounts of recycled water and associated actions to convey and apply fresh water to Utility District lands. The project is located roughly between Woodfords and the Nevada state line, and includes Diamond Valley, in Alpine County, California, and adjacent areas in Douglas County, Nevada.

Wildlife habitat resources include irrigated pasture, Great Basin scrub, riparian, and forested habitats. Significant natural resources include stream and reservoir habitat for cold water fisheries, deer winter range, and habitat for sensitive species. The West Fork of the Carson River, Indian Creek, Indian Creek Reservoir, and Harvey Place Reservoir are within the project boundaries. The following are our concerns:

Sensitive Species:

The DEIR fails to provide mitigation that reduces impacts to sensitive species to a level that is below significance. The DEIR identifies 39 special status species that may be impacted by the project. Table 11-6 further identifies that there will be potential adverse impacts associated with a large number of the project components and these impacts will not be reduced below a level of significance, before or after mitigation.

The Federal Endangered Species Act requires that impacts to listed species be reduced to the greatest extent practicable, whereas, the state Endangered Species Act (ESA) requires that the impacts be "fully mitigated". We recommend that the DEIR be revised so that it contains the means to either avoid impacts to state-listed species, or fully mitigate the project's impacts.

Deer:

36

30

The DEIR fails to discuss the project's potential impacts to migratory deer. The DFG maintains maps of important habitat areas for migratory deer throughout the state. The project site is located in an area designated as winter range for the Carson River deer herd. The Carson River herd has experienced significant loss of winter range habitat over the years. The proposed project is likely to exacerbate the loss of limited winter range habitat. For this reason, we recommend that the DEIR be revised to describe the potential loss of winter range habitat resulting from the conversion of native rangeland to irrigated pasture. We also

Conserving California's Wildlife Since 1870

Mr. Hoggatt

recommend that the DEIR be revised to contain measures that reduce or mitigate the loss of winter range habitat to a level that is less than significant. Additionally, we recommend that the DEIR be revised to include a discussion of how any proposed water conveyance structures (particularly large ditches) may create barriers to deer movement and how these impacts might be reduced to a level that is not significant.

Water Quality:

31

31

The project has the potential to affect water quality in the West Fork of the Carson River, as well as other tributary streams. Degradation of water quality in the West Fork Carson River and other streams may occur as a result of increases in recycled water deposition on currently permitted lands, as well as expansion of the number of acres of permitted lands. Degradation in water quality will have an effect on fish that inhabit these streams.

We recommend that the DEIR be revised to address the potential for recycled water to enter natural freshwater bodies through runoff from irrigated pastures, or via leaks or spills from conveyance facilities. The DEIR should contain a means of either avoiding degradation of water quality, or mitigating the effect below a level that is significant.

Lastly, the DEIR should consider and analyze whether implementation of the proposed project will result in reasonably foreseeable potentially significant impacts subject to regulation by the DFG under Section 1600 et seq. of the Fish and Game Code. In general, such impacts result whenever a proposed project involves work undertaken in or near a river, stream, or lake that flows at least intermittently through a bed or channel, including ephemeral streams and water courses. Impacts triggering regulation by the DFG under these provisions of the Fish and Game Code typically result from activities that:

- Divert, obstruct, or change the natural flow or the bed, channel or bank of any river, stream, or lake;
- Use material from a streambed; or
- Result in the disposal or deposition of debris, waste, or other material where it may pass into any river stream, or lake.

In the event implementation of the proposed project involves such activities, and those activities will result in reasonably foreseeable substantial adverse effects on fish or wildlife, a Lake or Streambed Alteration Agreement (LSAA) will be required by the DFG. Because issuance of a LSAA is subject to review under the California Environmental Quality Act (CEQA), the DEIR should analyze whether the potentially feasible mitigation measures will avoid or substantially reduce impacts requiring a LSAA from the DFG.

This project will have an impact to fish and/or wildlife habitat. Assessment of fees under Public Resources Code Section 21089 and as defined by Fish and Game Code Section 711.4 is necessary. Fees are payable by the project applicant upon filing of the Notice of Determination by the lead agency.

Pursuant to Public Resources Code Sections 21092 and 21092.2, the DFG requests written notification of proposed actions and pending decisions regarding this project. Written notifications should be directed to this office.

Thank you for the opportunity to review this project. If the DFG can be of further assistance, please contact Mr. Dan Gifford, Staff Environmental Scientist, telephone (209) 369-8851 or, Mr. Jeff Djongesen, Senior Environmental Scientist, telephone (916) 358-2919.

From: Robert Levy [mailto:roblevy@alpineso.com] Sent: Wednesday, August 26, 2009 9:36 AM To: Jimmie Hoggatt Subject: Master plan comments

Hi Jim,

I just wanted to make a comment regarding the river ranch/river view area. I currently own a 19ac property in River Ranch. Since all of our properties had the water rights sold away prior to the subdivision being created, many of us in the area are interested in some of the affluent being used for pasture irrigation. The sage brush is rapidly overtaking most of our pastures so we are interested in flood irrigation.

A pipe or ditch (some of which are still intact) would be an easy solution. Can you please inform me of the districts intent.

Sincerely,

Robert E. Levy

Undersheriff

Alpine County Sheriff's Office

STPUD Diamond Valley Ranch – Recycled Water Facilities Master Plan EIR – Public Comment - Turtle Rock Park 2 September 2009 – Alpine County, CA

Anders Hauge Presentation start 1315: end 1330

Shirley Tabor – 8 years ago when MP started – it was projected there was more effluent coming down the pipeline. Please state as to what flows were projected then, and what is flowing now.

Denise Murphy – water sample on Indian Creek – there has been no water for the past two years. Why? Need to know as to why there is no water. Hal response – Indian creek is dry. Now just tailwater in Indian creek down below the dam. STPUD has water rights in Indian Creek too but there is no water. Denise – no water even in spring! This is odd. Hal – we should go for a ride to see where IC comes onto District property.

Russ wickwire – Fish Biologist. Fish Indian Creek Reservoir and Indian Creek. What are realistic expectations will be able to meet the delivery. <<insert written comments from Mr. McGuire>> Legal ramifications that STPUD is responsible for: not to fall below minimum pool in ICR and adequate trout environment is to remain. ICR ICR ICR – nothing to do with EIR/Analysis/Setting/ or Proposed Projects/Components in the Master Plan. \*Flood waters being stored in ICR?

Ed Hinchel – Woodfords. Where does the water come from? It goes from SLT to farmers? Needs clarification of systems that are in operation. Hal provides summary of systems freshwater / recycled water.

Dan Sedergren - Currently there is insufficient recycled water for ranchers? Is all recycled water being utilized? You expand the land, where does the water come from? SLT is not going to grow! Where is the water going to come from? Water from effluent development is not going to increase. AH – Master Plan has to plan for the future in the event that water flows increase. \*Are there controls in place to preclude the addition of new land before the water is available? AH – response: the master plan has the "what ifs" included in the event changes occur in the future.

O Concerning Denise Murphy - Intent to use land that is being purchased is only being used in emergency situations only when I'm not getting water that I need?

Russ Wickwire – ICR over the years has less and less water – gets 555af/year. Even with full amount from IC, basically it does not keep up with evaporation and saturation in conveyance system – it goes down lower and lower and lower – soon to be mud puddle.

Zach Wood (with Alpine County) – description of components with some triggers and district might annex more land than what is existing. What is the expectation for annexation of lands in the foreseeable future? Where is this described in the document? AH – should an annexation occur by STPUD it would require modification to the Master
 Plan. Zach – where is this described in the document? 2 levels of master plan – greater

- master plan if that changes how much input would Alpine County residents get in that process? Subdivision is more tangible to forsee.
- Dan S. would Zach's comment (annexation) be included as a trigger?
- Will Richmond was oxgenation of ICR discussed in presentation? Will there be a public presentation planned? AH that was separate process.
- Russ Wickwire has fished lake quite a bit. Oxygenation is not functioning properly. Talked with samplers and they stated there is no oxygen in lake. System is not coming on during the daytime.
- Andy Lovell trying to understand the irrigation. If it is used in Alpine County what is it going to be used for? Flood irrigation or spray irrigation? AH – ag use. Andy – what about The Jungle? Is that all flood irrigation? Or Spray? Is it possible to create aerosol inc.

Where is The Jungle???

### 09/02/09

Public Comments to S. Tahoe Public Utilities District Re: Indian Creek Reservoir

What are the realistic expectations that the proposed-"future modifications of the present agreement documents" will be able to meet the "delivery volumes and timing (results) that will reflect unsatisfied contractual and other promised results at Indian Creek Reservoir (ICR) before environmental conditions become uncorrectable in the future. This reservoir produces one of the best trout quality and quantity fisheries in California (personal opinion of a CDF & G Fisheries Biologist)

How can the District state to support the recreational and trout environment values when earlier they would not take corrective actions early on to correct the potential problems? Some of these situations were contracted documents As early as (1968) when loan monies were given to Cal Dept. Water Resources (Davis-GrunskyAct) and by the Alpine County contract. (1967-first, 2002 last)

What are the legal ramifications that STPUD is responsibleto correct these legal breaches of contract and verbal promises? Some ofthese issues include not exceeding a minimum pool elevation, and ensuringadequate trout environment (water temperature, water oxygen, phosphoruslevels, etc.)

What are the preliminary results of the newly installed Hypolimnitic Oxygenation System acquired to promote higher aquatic oxygen level at ICR?

How realistic is it that ICR anglers can expect to catch trout in the near future? Today the lake has a tenuous trout population, but in recent years getting to them has become a problem. The boat anglers have very poor launching opportunities-inoperable cement boat ramp and treacherous/equipment damaging entry points along the lake shore. The shore angler has problems in the summer with a near shore aquatic vegetation barrier around most of the lakes perimeter that discourages anglers from fishing on the lake side of the dense vegetation and the water is too warm for trout in the shallow, inshore area.

| 17F | What has transpired with the promised construction of a new boat ramp on the more launching favorable east shore near the dam?                                                                                                                                                                                                                                                                                                                             |
|-----|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 179 | How will the District compensate the Bureau of Land Management for the continuing loss of campers at one of the best public campgrounds in the west (flushing toilets, hot-cold water, showers, heated restrooms and spacious camping sites)? The aesthetics of the lake and the limited boat launching areas has discouraged the anglers as well as the public to camp here (conversation with long term BLM campground hosts and personal observations). |
| 17h | Does the District, as it stated in its EIR, expect to continue to enjoy the existing cooperative venture with Alpine County when they don't honor and comply with their mutually agreed upon contract to comply with the minimum lake level and if not corrected soon, it will produce a aesthetic disappointing high sierra trout lake with a deteriorated trout fishery.                                                                                 |
| 171 | What is the District doing to promptly increase the quality and quantity of trout waters at ICR?                                                                                                                                                                                                                                                                                                                                                           |
| Fj  | What is the availability of the Districts W. Fork Carson River water<br>allotment (900 af) now being used on the 1400 acre Diamond Valley Ranch<br>that is owned by STPUD for irrigating lands to raise cattle? This water<br>source would solve many problems at ICR but to obtain this commodity may<br>entail a lengthy legal battle with downstream users. Why not start to take<br>the legal steps now before it is too late to save ICR values?      |
| 17K | What steps are being taken to allow flood waters to be stores in ICR if even for a short period of time until the snow melt is concluded? Let's be ready with all "ducks in order" otherwise we may miss the opportunities as we did in the 2007 flood?                                                                                                                                                                                                    |
| 171 | Why doesn't the District obtain a loan to purchase an adequate conveyance<br>system to provide better utilization of waters to ICR?<br>Do you know that Cal Department of Fish and Game's water rights were<br>purchased at Red Lake and Heenan Lake to maintain trout populations,                                                                                                                                                                        |

but at the same time release waters below their dams to maintain stream trout populations? These released waters may not have a water rights allotment and could be diverted into ICR.

17m Will the continued ICR environmental deteriorations have a bad public and professional perception on the District's past impressive worldwide reputation as a progressive public utility of the past or will the district rally "around the flag" and promptly correct the ICR environmental issues before it is too late to correct?

Send response to:

171

### STPUD RECYCLED WATER FACILITIES MASTER PLAN PUBLIC COMMENT 3 SEPTEMBER 2009 – STPUD BOARD ROOM

No comments.

- Board Comments -

Claudio - Can the optimization of application rates be modified? Are there rules? When pursue permitting for more land? What does this involve? AH responds.

Jones – anything significant from yesterday's meeting at Turtle Rock Park? AH responds.

Paul – one question regarding safety of aerosol from spray irrigation and associated health issues. AH responds. Richard passes out Bently photograph showing cener pivot rigs and hoses.

Jones – when this was started there were other items included that were nice to dos. How could we incorporate these into master plan? Can they be done separate?

COUNTY OF ALPINE Board of Supervisors

September 4, 2009

South Tahoe Public Utility District 1275 Meadow Crest Drive South Lake Tahoe, CA 96150

Re: Recycled Wastewater Facilities Master Plan Draft Environmental Impact Report

Dear Sirs:

The Alpine County Board of Supervisors appreciates the opportunity to comment on the Recycled Wastewater Facilities Master Plan Draft Environmental Impact Report. As part of the preparation of the DEIR the Board of Supervisors provided comments during the public scoping period. The Board would like to again submit our comments as follows:

1. The County supports optimizing the application rate for recycled water used for irrigation purposes on existing permitted lands in Alpine County. 2. Alpine County has concerns with providing water to irrigators in Nevada. Rather the County urges STPUD to pursue improvements to the infrastructure that would allow for application to existing permitted lands that are not receiving recycled water. Tailwater detention systems should be included in all alternatives. The County supports transferring water rights to ICR to improve water quality and habitat. The County supports using piped irrigation technologies for the application of recycled water. Pressurized water systems are highly desirable in providing efficient delivery of recycled water to permitted areas. The County urges the district to consider expansion of the existing hydrant system to provide additional access points closer to residential development in the Mesa Vista and River Ranch locations. The County supports the recycled water wholesale program for new permitted 8. users only. Maintaining historical relationships with existing permitted irrigators is critical. 9. The County encourages STPUD to work with NDEP regarding any diversion of recycled water to Nevada. 10. The County supports the transfer of water rights to storage in Indian Creek. Increased flows would improve water quality. The County supports transferring water from other locations in the County including Red Lake to improve water quality and habitat. The County supports the development of biomass and/or wetland sod and seed production, native plant nursery and other economic development opportunities.

Recycled Wastewater Facilities Master Plan DEIR September 4, 2009 Page 2

The County does not have specific comment on the document at this time. The District should be aware that the County will work with the District on permitting and monitoring future Master Plan projects that are under our jurisdiction. Some of the projects described in the DEIR will require entitlements from Alpine County and additional CEQA compliance documentation. The three immediate projects that the District is preparing to implement and are described in project level detail do not require County approvals or further CEQA documentation.

The County hopes that the productive working relationship with the District will continue as the District moves forward with implementation of the Recycled Wastewater Facilities Master Plan.

Sincerely,

Phillip D. Bennett, Chair Alpine County Board of Supervisors

Jim Hoggatt General Manager South Tahoe PUD 1275 Meadow Crest Drive South Lake Tahoe, CA 96150

10- ALP-88-PM var South Tahoe PUD Recycled Water Facilities Master Plan EIR SCH #2007042116

Dear Mr. Hoggatt:

The Department of Transportation (Caltrans) appreciates the opportunity to review and comment on proposed South Tahoe Public Utilities District Recycled Water Facilities Master Plan Environmental Impact Report. The project proposes three projects to address the reuse and retention of recycled water generated in the South Lake Tahoe area of El Dorado County in Alpine County CA and neighboring Douglas County NV.

Caltrans has evaluated Chapter 12 Traffic and Circulation. As this is a planning EIR, Caltrans as a responsible agency has no comment at this time, but reserves comment on any project level environmental study. As several of the proposed water conveyances will cross State Routes 88 and 89 at various locations, an encroachment permit will be required of the lead agency.

If you have any questions or would like to discuss our comments in more detail, please contact Michael Robinson at (209) 948-7575 (e-mail: Michael robinson@dot.ca.gov) or me at (209) 941-1921.

Sincerely

DANIEL H. BREWER, Chief Office of Rural Planning & Administration

## State Water Resources Control Board

Division of Financial Assistance 1001 I Street, Sacramento, California 95814• (916) 341-5700 Mailing Address: P.O. Box 944212 • Sacramento, California 94244-2120 FAX (916) 341-5707 • http://www.waterboards.ca.gov

Arnold Schwarzenegger Governor

SEP 8 2009

Mr. Jim Hoggatt South Tahoe Public Utility District 1275 Meadow Crest Drive South Lake Tahoe, CA 96150

Dear Mr. Hoggatt:

DRAFT ENVIRONMENTAL IMPACT REPORT (EIR) FOR SOUTH TAHOE PUBLIC UTILITY DISTRICT (DISTRICT); RECYCLED WATER FACILITIES MASTER PLAN (PROJECT); EL DORADO COUNTY; STATE CLEARINGHOUSE NO. 2007042116

We understand the District is pursuing Clean Water State Revolving Fund (CWSRF) financing for the Master Plan Project 1-Diamond Valley Ranch Emergency Retention/Irrigation Field (CWSRF No. C-06-5611-110), and the Master Plan Project 2-Recycled Effluent Pipeline Reroute (CWSRF No. C-06-5608-110). As a funding agency and a state agency with jurisdiction by law to preserve, enhance, and restore the quality of California's water resources, the State Water Resources Control Board (State Water Board) is providing the following information on the EIR prepared for the Project.

Please provide us with the following documents applicable to the proposed Project: (1) Two copies of the draft and final EIR, (2) a resolution certifying the EIR, adopting a Statement of Overriding Considerations (SOC) and a Mitigation Monitoring and Reporting Program (MMRP), and making California Environmental Quality Act (CEQA) findings, (3) all comments received during the review period and the District response to those comments, (4) the District's adopted MMRP and SOC, and (5) the Notice of Determination filed with the Governor's Office of Planning and Research. In addition, we would appreciate notice of any hearings or meetings held regarding environmental review of any projects to be funded by the State Water Board.

The CWSRF Program is partially funded by the U.S. Environmental Protection Agency (USEPA) and requires additional "CEQA-Plus" environmental documentation and review. Three information sheets are included that further explain the environmental review process and additional federal requirements in the CWSRF Program. The State Water Board can consult directly with agencies responsible for implementing federal environmental laws and regulations. Any environmental issues raised by federal agencies or their representatives will need to be resolved prior to State Water Board approval of a CWSRF funding commitment for the proposed Projects above. For further information on the CWSRF Program, please contact Ms. Michelle L, Jones at (916) 341-6983.

It is important to note that prior to a CWSRF funding commitment, projects are subject to provisions of the Federal Endangered Species Act and must obtain approval from the U.S. Fish and Wildlife Service (USFWS), and/or National Marine Fisheries Service (NMFS) for any potential effects to special status species.

California Environmental Protection Agency

2401

Please be advised that the State Water Board can consult with USFWS, and/or NMFS on behalf of the District regarding all federal special status species the Projects above have the potential to impact. The District will need to identify whether these will involve any direct effects from construction activities, or indirect effects, such as growth inducement, that may affect federally-listed threatened, endangered, or candidate species that are known, or have a potential to occur on-site, in the surrounding areas, or in the service area.

In addition, CWSRF projects must comply with federal laws pertaining to cultural resources, specifically Section 106 of the National Historic Preservation Act (NHPA). The State Water Board has been delegated responsibility for carrying out the requirements of Section 106 under a Nationwide Programmatic Agreement executed for the CWSRF Program by the USEPA, the Advisory Council on Historic Preservation, and the National Conference of State Historic Preservation Officers.

As stated above, the State Water Board has responsibility for ensuring compliance with Section 106, and the State Water Board Cultural Resources Officer (CRO) consults directly with the California State Historic Preservation Officer (SHPO). SHPO consultation is initiated when sufficient information is provided by the CWSRF applicant for projects having potential impacts to cultural resources. Please contact the State Water Board CRO Ms. Cookie Hirn at (916) 341-5690, to find out more about the requirements, and any questions on beginning the Section 106 compliance process, as applicable. Note that the District will need to identify the Area of Potential Effects (APE), including construction, staging areas, and depth of any excavation.

Please provide the CRO with a copy of a current records search, including maps that show all recorded sites and surveys in relation to the APE for the two project areas. Also include the cultural resources studies that were conducted for previous wastewater treatment plant expansion projects. The APE is three dimensional, and includes all areas that may be affected by these Projects. The APE includes the surface area and extends below ground to the depth of any Project excavations. The records search request should be made for an area larger than the APE. The appropriate area varies for different projects, but should be drawn large enough to provide information on what types of sites may exist in the vicinity.

Native American and Interested Party Consultation is required for Section 106 compliance:

- Project descriptions and maps should be sent to the Native American Heritage Commission (NAHC). The NAHC will provide a list of Native American tribes and individuals that are culturally affiliated with the project areas and recommend they all be contacted.
- Project descriptions and maps should be sent to everyone on the list provided by the NAHC, asking for information on the project areas.
- Similar letters should be sent to local historical organizations.
- Follow-up contact should be made by phone, if possible, and a phone log should be included.

California Environmental Protection Agency

Mr. Jim Hoggatt

240

741

- 3 -

Comments from the NAHC, local tribes, and historical organizations affiliated with the Project area, as well as District response to these comments should be included in the submittal to the CRO. The NAHC can be contacted at:

915 Capitol Mall, Room 364 Sacramento, CA 95814 (916) 653-4082

Other federal requirements pertinent to the Projects under the CWSRF Program include the following:

A. Compliance with the Migratory Bird Treaty Act (Act): List any birds protected under this Act that may be impacted by the Projects and identify conservation measures to minimize impacts.

Following are specific comments on the EIR:

 Due to the structure of the Environmental Analysis section, it is difficult to determine whether the Master projects have been adequately evaluated at a project specific level. State Water Board staff requests that the Environmental Analysis section in the Master Plan be restructured to include separate analyses distinct from the programmatic-level analysis for the Projects to be funded by the CWSRF Program. Please include project specific analyses.

 To comply with Section 106 of the NHPA, please include Record Search maps with all sites and surveys mapped in relation to the project sites and APEs, as well as all staging areas and depths of construction.

3. Mitigation measures GW-1A and GW-1B state that the District will "Determine a Nutrient Neutral Grazing Regime for the Diamond Valley Ranch" and "Determine Maximum Duration for Temporary Containment." Note that mitigation can not be deferred to a future date, as stated by CEQA Guidelines Section 15126.4(b). Please correct mitigation measures GW-1A and GW-1B to include specific, feasible actions that will improve adverse environmental conditions, be measurable to allow monitoring, and be enforceable, as stated by CEQA Guidelines Section 15370.

4. Mitigation Measure BIO-1 includes a requirement to conduct biological resource assessments. This measure is being applied to Components 11 and 19 that make up Master Plan 1 and 2. In order for Master Plan Projects 1 and 2 to be evaluated at project-level analyses, all mitigation measures for the Master Plan Projects have to include specific, feasible actions that will improve adverse environmental conditions, be measurable to allow monitoring, and must be enforceable as stated by CEQA Guidelines Section 15370. Change mitigation measure BIO-1 to comply with CEQA Guidelines Section 15370.

California Environmental Protection Agency

Recycled Paper

Mr. Jim Hoggatt

14F

241

4- SEP 8 2009

5. Standard Practice (SP)-30) Pre-construction Surveys for Nesting Raptors and Wildlife Nurseries is being applied to Master Plan Projects 1 and 2. SP-30 is not feasible mitigation for this impact. As stated earlier, mitigation includes specific, feasible actions that will improve adverse environmental conditions, be measurable to allow monitoring, and must be enforceable, as stated by CEQA Guidelines Section 15370. Change mitigation measure SP-30 to comply with CEQA Guidelines Section 15370.

6. Page 13-16 states that "Sensitive receptors are located over one half mile from the closest sensitive receptors and odor complaints will not cause odor complaints." Please clarify this statement to correctly reflect the location of sensitive receptors from the project sites, and the potential to receive odor complaints caused by the Project.

State Water Board staff has no further comments on the EIR at this time. Thank you once again for the opportunity to review the District's EIR. If you have any questions or concerns, please feel free to contact me at (916) 327-9401, or contact Ms. Justine Herrig at (916) 327-9117.

Sincerely.

Lisa Lee Environmental Scientist

September 9, 2009

Paul Sciuto Assistant General Manager South Tahoe Public Utility District 1275 Meadow Crest Drive South Lake Tahoe, CA 96150

### REVIEW OF THE DRAFT ENVIRONMENTAL IMPACT REPORT FOR SOUTH TAHOE PUBLIC UTILITY DISTRICT RECYCLED WATER FACILITIES MASTER PLAN, (WDID 6A095900700).

The California Regional Water Quality Control Board, Lahontan Region (Water Board) staff reviewed the Environmental Impact Report (EIR). We limited our review to looking at the three project level descriptions in the EIR which we believe are the following (as listed on page 1-5) by EIR Project number.

- 11. Construct irrigation fields with pumping back to Harvey Place Reservoir
- 18. Optimized application rate on existing irrigated lands
- 19. Pursue permitting of more land in Alpine County.

The following are our comments on the three projects.

For the construction of irrigation fields with the ability to pump back to Harvey Place Reservoir and to pursue additional permitting of more land in Alpine County (item numbers 11 and 19), the Water Board will require a Report of Waste Discharge that will describe field conditions and how the pumping will be done. Individual waste discharge requirements will be produced for all new fields that will be irrigated with recycled wastewater.

For the optimized application rate on existing irrigated land, the Water Board staff has reviewed the Nutrient Management Plan. The Nutrient Management plan may need to be adjusted to comply with California laws, which will be reflected in Waste Discharge Requirements. Our main concern is in Section 4.2 *Nutrient Balance Comparison* section, the last sentence states, "The drinking water standard (threshold) is 10 mg/l, however the DISTRICT feels that it is prudent to monitor for a "trigger threshold" of 7 mg/l allowing for alternative management opportunities prior to reaching the regulatory threshold." The Water Board will use the trigger of a statistically significant increase in

California Environmental Protection Agency

🖇 Recycled Paper

### Paul Sciuto

nitrate as nitrogen or other constituent of concern (in the recycled wastewater) contributed from the use of recycled wastewater as a trigger to consider alternative management opportunities.

If the District wishes to maintain that the 7mg/l is prudent for the Water Board to use as a trigger for response, then the California Environmental Quality Act document should include an analysis to support the use of 7mg/l as an acceptable threshold. This analysis must consider other sources, alternatives and reasonable control measures. Otherwise we encourage the Nutrient Management plan in the EIR reflect that the Water Boards may impose more stringent trigger-valves than proposed in the EIR.

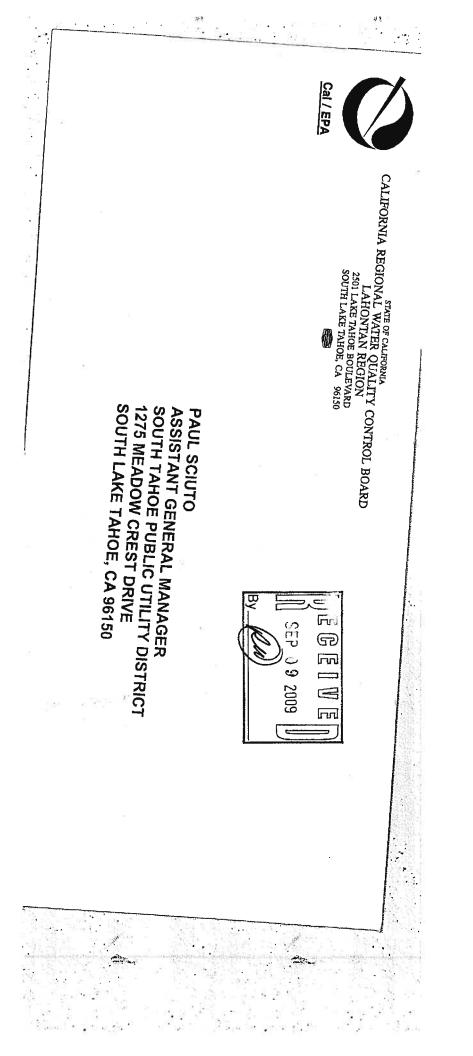

If you have questions regarding this matter please contact me at (530) 542-5467, or Alan Miller, Chief, North Basin Regulatory Unit, at (530) 542-5430.

# S.T.P.U.D. Board Report from Director Claudio

Board Workshop Wednesday, July 22, 2009 at the District Boardroom.

These notes were compiled by Richard Solbrig and Ernie Claudio

Attendees: Richard Solbrig, Mary Lou Mosbacher, Dale Rise, Ernie Claudio, Jim Jones, Eric Schafer, John Runnels, Peggy Cocores, Ken Kurtzweiler, John Cefalu, Chris Cefalu, Todd Williams, Mary Jane Sanchez.

- 1. Solar Energy:
  - a. <u>Return on Investment (ROI):</u> The District will continue to consider green projects, with an appropriate ROI required before pursuing them.
  - b. <u>Smaller Installations:</u> It was mentioned that the District might invest in some smaller more cost effective solar units in order to gain experience with solar technology.
  - c. <u>Security:</u> Check on Homeland security grants for fencing to protect solar installations.
  - d. <u>Customer Survey:</u> Director Schafer suggested a question be placed on the next customer survey about their willingness to invest in solar energy.
  - e. Passive Solar: Passive solar should be considered for new District projects.
  - f. **Future Plans:** It was suggested that a budget item for solar be included in the 10/15/25 year plans.
  - g. **Power Purchase Agreement (PPA):** Check with companies offering PPA's on a regular basis to see if the deals are getting better.
  - h. Energy Buy-Back Cap: The State will be requiring that local power providers buy back surplus solar energy from its customers. Check to see where the cap is.

# S.T.P.U.D. Board Report from Director Claudio

### 2. Water Meters:

- a. <u>Water Auditor</u>: Complete a detailed description of the duties of the Water Auditor and the associated costs.
- Future Plans: Include a budget items for <u>water meter installations</u> in the 10/15/25 year plans.
- c. <u>Future Plans</u>: Include a budget items for <u>water line replacements</u> in the 10/15/25 year plans.
- d. <u>Public Outreach:</u> Inform the District customers about the water meter law, the costs and the schedule.
- e. Water Rates: Complete at water rate study by January 2010.
- f. <u>Water Audit:</u> It was suggested that the District audit the current commercial users to see if any users are wasting water.

## 3. Budget Savings Cost Measures:

- a. <u>Travel Costs:</u> It was suggested that we look into the possibility of reducing some of the travel expensed associated with non-required training events and information seminars.
- b. <u>Medical Costs</u>: It was suggested the District examine different options to reduce medical costs when the current MOU's are doe to expire. For example, the possibility of raising the healthcare co-pay with the incentive of a \$100 bonus for each employee who does not have a doctor's visit for that month. This is being done at the Lake Oroville Area PUD.
- c. <u>Agenda Meetings</u>: It was suggested that we look into the possibility of having some agenda meetings without attorney services.
- d. <u>Changing Auditors:</u> It was suggested that we look into the possible benefits of changing auditors every five years.

### 4. Use of Consultants:

- a. Limited Term Retirees: It was suggested that we look into the possibility of using the limited term hiring of a retiree instead of using a consultant.
- b. **Consultant Pool:** It was suggest that we look into the possibility of using a consultant pool with reduced rates.

### 5. Legal Services RFP:

- a. Legal Services RFP: It was suggested that we put out and RFP for legal services for non-special venues.
- b. <u>Ad Hoc Committee:</u> It was suggested that we create an ad-hoc committee to define the scope of services and the desired time period for these legal services.

# 6. Need for additional workshops was acknowledged.

Agenda Item Questions

### Consent Calendar:

- 7. Item B Unpaid Assessments:
  - a. How often is this done?
  - b. What percent of these monies are we expecting to recover?
  - c. Can we end up in court because of a dispute over Prop.218?
- 8. Item D GIS Maintenance and Development:
  - a. How is this mapping system different than the InfaMap system?
  - b. Will the District need the services of this contractor next year?
  - c. How many "third-party" software purchases are needed?
  - d. Is the development of the "synchronize" tool a one-time cost?
  - e. What advantage does a GPS location of waters meters have over the system the District presently uses?
  - f. Who presently updates the GIS table for customer accounts?

# S.T.P.U.D. Board Report from Director Claudio

- g. How many times is the permit table in GIS updated annually?
- h. How many times is the easement table in GIS updated annually?
- i. After the Engineering Specialist are trained will the District need any future updating services from this contractor?
- j. Who will cover the costs of renting a laser rangefinder if the contractor needs one?
- k. How long will it take to complete the GPS Survey (item 3.10)?
- 1. In the past, how has the District been updating hydrant locations and attributes?
- m. How much will it cost to deploy the ArcReader access tool?
- n. How often has the District needed to edit the service lateral line data?
- 9. Item E 2009 Water Meter Installation Project
  - a. What are the present estimated costs for: 1) meter purchase, 2) meter installation, 3) engineering?

Recycled Water Facilities Master Plan ENVIRONMENTAL IMPACT REPORT

The application and use of recycled water in the Tahoe Basin is forbidden because of the hazarders associated with this material. The use of sprinkler to apply recycled water in Alpine county is mentioned twice (see attachments) in EIR report. Applying recycled water to the ground is one thing, applying it to the atmosphere, where it can blow miles down-wind, is potentially dangerous. Does the District want to assume this liability?

### 4.1.5.2 Irrigation Method Efficiency

Irrigation efficiency varies with the method chosen for distribution. For the initial development of this NMP, surface (flood/furrow) irrigation and spray irrigation (hand/wheel lines or center-pivot sprinklers) were analyzed. The efficiency rates are listed in Table 7 (Metcalf and Eddy 1991).

| Irrigation Method | Efficiency (%) |
|-------------------|----------------|
| Surface           | 65             |
| Spray             | 70             |

Table 7. Irrigation Efficiency (Metcalf and Eddy 1991)

## 4.1.6 Limiting Factor Determination

The hydraulic loading rates based on irrigation water, nitrogen limits, and soil permeability were calculated for the following four combinations:

- alfalfa/surface
- alfalfa/spray
- pasture grass/surface, and
- pasture grass/spray.

There were three loading rates (consumption, nitrogen, and permeability) calculated for each of the four combinations listed above. The comparison of the three hydraulic loading rates ensures that the quantity of recycled water applied to the crops will adequately fulfill specific crop requirements, safely percolate through the soil profile, and protect groundwater. In comparing these hydraulic loading rates, the lowest value of the three (maximum allowable application rate of recycled water) is the primary limiting factor. Please see Section 5.0 Hydraulic Loading for more in-depth discussion.

2 ...

Harvey Channel is to direct Indian Creek flows (exceeding the conveyance capacity of the Upper Dressler Ditch) around the Harvey Place Reservoir. The Upper and Lower Harvey Channels carry freshwater only and enter Indian Creek below the dam of the Harvey Place Reservoir.

# 30. Irrigate the "Jungle" with Recycled Water

The District obtained land known as the "Jungle" with its purchase of the Diamond Valley Ranch. The jungle is located northwest of the Snowshoe Thompson No. 2 Ditch and north of the Millich Ditch. At its nearest point the jungle is approximately 1,100 feet from the West Fork of the Carson River. The jungle is not currently irrigated and is characterized as sloping and bottom valley land. There are approximately 150 acres that will be irrigated with recycled water once infrastructure is constructed to convey water to this area. The need for additional lands may arise from loss of lands currently irrigated with recycled water due to subdivision or some other cause, or by increased annual volume of recycled water resulting from growth in the District's service territory. Spray irrigation methods will be utilized as the irrigation method. Water will be supplied under pressure from a pipeline branching off the existing C-Line or from the proposed pressurized line that would pump water back to Harvey Place Reservoir (Component 11).

# 31. Divert Stormwater Flow Away from Harvey Place Reservoir to Indian Creek Reservoir

This project component constructs a ditch near the southeast corner of the Harvey Place Reservoir to intercept stormwater and drainage flows that currently flow into the Harvey Place Reservoir and divert them to ICR. The purpose will be to reduce stormwater flow into the Harvey Place Reservoir thereby increasing the available recycled water storage volume of the Harvey Place Reservoir. Another benefit of this project component will be to increase the amount of freshwater entering ICR. A method of sediment control may be necessary to reduce sediment loading in ICR. This component will be implemented only if recycled water volume increases and additional storage volume for recycled water in Harvey Place Reservoir is needed, or if additional freshwater is needed in ICR to improve water quality and meet

| 3c                | 8/12/2009 | Kent Smith, Habitat<br>Conservation<br>Program Manager,<br>California<br>Department of Fish<br>and Game | DEIR fails to discuss the project's potential<br>impacts to migratory deer. The project site is<br>located in an area designated as winter range for<br>the Carson River deer herd. The proposed project<br>is likely to exacerbate the loss of limited winter<br>range habitat. Recommended that the DEIR be<br>revised to describe the potential loss of winter<br>range habitat resulting from the conversion of<br>native rangeland to irrigated pasture. | The analysis in Chapter 11 has been revised to<br>include modifications to the analysis and<br>clarifications of mitigation measure BIO-4A (Page<br>D-55) for bridges over existing conveyance facilities<br>to allow for passage of migrating deer resulting in a<br>less than significant impact. Loss of winter range<br>was included in the DEIR analysis and determined<br>that no significant impact would result to deer<br>populations.<br>Discussions with DFG clarified that no conversion<br>winter range would occur, but that projects may be<br>implemented in winter range habitat. A summary of<br>DFG meetings and consultation is included in<br>Appendix K. Loss of habitats would be offset as<br>defined by SP-25 as outlined in Appendix D and will<br>result in less than significant impacts. |
| 3d                | 8/12/2009 | Kent Smith, Habitat<br>Conservation<br>Program Manager,<br>California<br>Department of Fish<br>and Game | Recommend DEIR be revised to contain<br>measures that reduce or mitigate the loss of<br>winter range habitat for deer.                                                                                                                                                                                                                                                                                                                                        | See Comment 3c.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| 3e                | 8/12/2009 | Kent Smith, Habitat<br>Conservation<br>Program Manager,<br>California<br>Department of Fish<br>and Game | Recommend DEIR be revised to include a discussion of how any proposed water conveyance structures may create barriers to deer movement and how those impacts may be reduced.                                                                                                                                                                                                                                                                                  | See Comment 3c.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| 3f                | 8/12/2009 | Kent Smith, Habitat<br>Conservation<br>Program Manager,<br>California<br>Department of Fish<br>and Game | Recommend DEIR be revised to address the<br>potential for recycled water to enter natural<br>freshwater bodies through runoff from irrigated<br>pastures, or via leaks or spills from conveyance<br>facilities. DEIR should contain measures to<br>either avoid water quality degradation, or<br>mitigate the effect below a level that is<br>significant. | <ul> <li>The potential for recycled water to enter freshwater bodies is less than significant through implementation of standard practices that are required by law or committed to by the District as part of the project component. These standard practices include:</li> <li>SP-11 Erosion Control/Stormwater Pollution Prevention Plan (outlines protection of water bodies during construction and operations);</li> <li>SP-17 Pipeline Design Features in Active Fault Zones (requires automatic shut off valves to control and isolate impacts from pipe breaks);</li> <li>SP-21 Temporary Containment and Impoundment Siting and Design (requires adequate freeboard to reduce risk of overtopping during a seismic event);</li> <li>SP-33 Surface and Groundwater Protection Plan (implements tailwater management and containment practices, 25 foot setbacks and buffers for surface water quality protection, release prevention and public protection strategies, and monitoring actions);</li> <li>SP-34 Application and Temporary Containment Infrastructure Maintenance and Monitoring (Visual inspection after high runoff events and periodic maintenance to prevent degradation of surface water quality from slope or levee failure or impoundment spills); and</li> <li>SP-35 Conveyance Infrastructure Maintenance Plan (annual inspections of pipelines and periodic maintenance to prevent degradation of surface water quality from pipeline failure).</li> </ul> |

|                   | Table P-1 |                                                                                                         |                                                                                                                                                                                                                                                                                                                                                |                                                                                                                                                                                                                                                                                                                                                                                                                                                  |  |

| 3g                | 8/12/2009 | Kent Smith, Habitat<br>Conservation<br>Program Manager,<br>California<br>Department of Fish<br>and Game | DEIR should consider whether implementation of<br>the proposed project will result in reasonably<br>foreseeable potentially significant impacts subject<br>to regulation by CDFG under Section 1600 et<br>seq. of Fish and Game Code.                                                                                                          | Projects that potentially impact rivers, streams or<br>lakes require the issuance of a Lake or Streambed<br>Alteration Agreement (LSAA) from CDFG. This<br>agreement is required by law and is a standard<br>practice of the Recycled Water Facilities Master<br>Plan. Projects 1, 2, 12 will not require a LSAA.<br>Future Master Plan projects may require a LSAA.<br>The district will comply with this requirement. See<br>comment 3h below. |  |
| 3h                | 8/12/2009 | Kent Smith, Habitat<br>Conservation<br>Program Manager,<br>California<br>Department of Fish<br>and Game | In the event implementation will result in<br>reasonably foreseeable substantial adverse effects<br>on fish or wildlife, a Lake or Streambed<br>Alteration Agreement (LSAA) will be required.<br>DEIR should analyze potentially feasible<br>mitigation measures to avoid or substantially<br>reduce impacts requiring a LSAA from<br>theCDFG. | The EIR has been revised to include modifications to<br>the analysis stating whether the actions will require a<br>LSAA. Implementation of Component 11will<br>require a LSAA to be issued by CDFG for bypass<br>pipeline alternative alignments A and C.<br>The EIR includes language clarifying this<br>requirement on Page 11-49.                                                                                                             |  |
| 3i                | 8/12/2009 | Kent Smith, Habitat<br>Conservation<br>Program Manager,<br>California<br>Department of Fish<br>and Game | This project will have impacts to fish and/or<br>wildlife habitat. Assessment of fees under Public<br>Resources Code Section 21089 and as defined by<br>Fish and Game Code Section 711.4 is necessary.<br>Fees are payable by project applicant upon filing<br>NOD.                                                                            | Upon filing the Notice of Determination (NOD), fees<br>will be paid to CDFG in accordance with Public<br>Resources Code Section 21089 as defined by Fish<br>and Game Code Section 711.4                                                                                                                                                                                                                                                          |  |
| 3j                | 8/12/2009 | Kent Smith, Habitat<br>Conservation<br>Program Manager,<br>California<br>Department of Fish<br>and Game | Pursuant to Public Resources Code Sections<br>21092 and 21092.2 the CDFG requests written<br>notification of proposed actions and pending<br>decisions.                                                                                                                                                                                        | In compliance with Public Resources Code Section<br>21092 and 21092.2 CDFG will receive written<br>notification of the proposed actions and pending<br>decision required for adoption and execution of the<br>Recycled Water Facilities Master Plan.                                                                                                                                                                                             |  |

| 4a                | 8/26/2009 | Robert Levy,<br>Undersherrif, Alpine<br>County Sheriff's<br>Office | Owns 19 acres in River Ranch - since properties<br>water rights were sold away prior to the<br>subdivision being created, many are interested in<br>some of the effluent being used for pasture<br>irrigation. Sage brush is overtaking pastures so<br>interested in flood irrigation. A pipe or ditch<br>would be an easy solution. Can you please<br>inform me of District's intent. | The application of recycled water in the River Ranch<br>area is not a project of the Recycled Water Facilities<br>Master Plan. The comment will be provided to the<br>District Board for their consideration. Future<br>modification of the Master Plan requires<br>environmental documentation and public scoping.<br>The District's intent is outlined in the Sections 9<br>through 13 of the Recycled Water Facilities Master<br>Plan. Component 6 - provide Pressurized Recycled<br>Water to the Ranchettes addresses this comment.                                                                                                                                                |  |
| 5a                | 9/2/2009  | Shirley Tabor                                                      | Eight years ago it was projected more effluent<br>coming down the pipe. Please state what flows<br>were projected then, and what is flowing now.                                                                                                                                                                                                                                       | Section 5 of the Recycled Water Facilities Master<br>Plan outlines three different methods used for the<br>projection of flows through 2028 and presents annual<br>flows for years 1997 through 2006.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |  |
| 6a                | 9/2/2010  | Denise Murphy                                                      | There has been no water in Indian Creek for two years. Why?                                                                                                                                                                                                                                                                                                                            | There are no flows in Indian Creek because of drought conditions.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |  |
| 7a                | 9/2/2011  | Russ Wickwire                                                      | What are the realistic expectations that the<br>District will be able to meet delivery (fish in ICR<br>and Indian Creek). What are the legal<br>ramifications that District is responsible for<br>maintaining minimum pool elevation of water in<br>ICR and the District's responsibility to maintain<br>adequate trout habitat. Flood waters being stored<br>in ICR?                  | Comment does not raise significant environmental<br>issues related to the Recycled Water Facilities<br>Master Plan and no response is required.<br>Two project components of the master plan,<br>Component 17 - Increase Snowshoe Thompson No.<br>1 Conveyance Capacity and Component 24 -<br>Transfer Additional Water Rights to Storage in<br>Indian Creek Reservoir would provide for additional<br>flows to reach ICR, which could potentially raise the<br>water levels in ICR and subsequently enhance the<br>water quality and habitat of the fresh water fishery.<br>The concern over management of ICR has been<br>submitted to the District Management for<br>consideration. |  |

| 8a                | 9/2/2012  | Ed Hinchel     | Where does the water come from? It goes from SLT to farmers? Needs clarification of systems in operation.                                                                                                                 | The recycled water is Secondary-23 treated<br>wastewater generated from the District's Wastewater<br>Treatment Plant (WWTP) located in South Lake<br>Tahoe, CA and managed in accordance with the<br>Waste Discharge Requirements from the State Water<br>Resources Control Board. Board Order R6T-2004-<br>0010.                                                                                                                                                                                                                                                                                                                                                                           |  |
|                   |           |                |                                                                                                                                                                                                                           | The recycled water is delivered to Alpine County ranchers under contract with the District.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |  |
| 9a                | 9/2/2013  | Dan Sedergren  | Currently there is insufficient recycled water for<br>ranchers? Is all recycled water being used? You<br>expand the land, where does the water come<br>from? Water from effluent development is not<br>going to increase. | The recycled water volume supplied by the District's<br>WWTP is used in its entirety. Please see the analysis<br>in Section 5 of the Recycled Water Facilities Master<br>Plan, which calculates the current supply and<br>demand as well as the protected supply and demand.                                                                                                                                                                                                                                                                                                                                                                                                                |  |
| 9Ь                | 9/2/2014  | Dan Sedergren  | Are there controls in place to preclude the addition of new land before the water is available?                                                                                                                           | The Recycled Water Facilities Master Plan does not<br>include the provision for the acquisition of new<br>lands, but does provide for the permitting of lands<br>owned by the District and irrigators in Nevada to<br>received recycled water (Project Components 1, 2<br>and 19).                                                                                                                                                                                                                                                                                                                                                                                                          |  |
| 10a               | 9/2/2015  | Denise Murphey | Is it the intent of the District to use land that is<br>being purchased to only be utilized in emergency<br>situations and not when I'm not getting water that<br>I need?                                                 | Indian Creek contains freshwater that is not used for<br>District irrigation activities. Seven irrigation fields<br>will be constructed on Diamond Valley Ranch. Two<br>of the seven fields will also be developed for<br>temporary containment for recycled water in the<br>event of a flood (Project Component 11). The<br>Diamond Valley Ranch will continue to be irrigated<br>freshwater and grazed with cattle. Upon completion<br>of Component 11, the fields will be irrigated with<br>recycled water exported from the plant in South Lake<br>Tahoe (WWTP) and the cattle will be removed. See<br>pages 2-41 through 2-43 of the EIR for a complete<br>description of the project. |  |

|                   |          |                                                    | Table P-1                                                                                                                                                                                                             |                                                                                                                                                                                                                                                                                                         |

| 11a               | 9/2/2016 | Russ Wickwire                                      | ICR has less and less water. Even with full<br>amount in Indian Creek, basically it does not<br>keep up with evaporation and saturation in<br>conveyance system.                                                      | See response to comment 7a.                                                                                                                                                                                                                                                                             |
| 12a               | 9/2/2017 | Zach Wood                                          | Description of components with some triggers<br>and District might annex more land than what is<br>existing. What is the expectation of lands to be<br>annexed in the foreseeable future?                             | The annexation of additional lands into the South<br>Tahoe PUD service boundary is not anticipated and<br>not included as a trigger in the Recycled Water<br>Facilities Master Plan.                                                                                                                    |
| 12b               | 9/2/2018 | Zach Wood, Alpine<br>County Planning<br>Department | Where is this in the document? Two levels of<br>Master Plan - greater Master Plan if that changes<br>how much input would Alpine County residents<br>get in that process? Subdivision is more tangible<br>to foresee. | Modifications of the Recycled Water Facilities<br>Master Plan requires public scoping and noticing<br>and the incorporation of comments from Alpine<br>County residents into the planning process. The<br>District intends on updating the Recycled Water<br>Facilities Master Plan on a regular basis. |
| 13a               | 9/2/2019 | Dan Sedergren                                      | Would annexation be included as a trigger?                                                                                                                                                                            | See Comment 12a. Annexation is not included as a trigger.                                                                                                                                                                                                                                               |
| 14a               | 9/2/2020 | Will Richmond                                      | Was oxygenation of ICR discussed in presentation? Will there be a public presentation planned?                                                                                                                        | The ICR oxygenation system was processed under a separate environmental document (Mitigated Negative Declaration, Clearinghouse number 2007102083). Public presentations are planned by the District.                                                                                                   |
| 15a               | 9/2/2021 | Russ Wickwire                                      | Oxygenation is not functioning properly in lake.<br>No oxygen in lake according to samplers.                                                                                                                          | Evidence was not provided that the oxygenation<br>system is not functioning properly in Indian Creek<br>Reservoir. The oxygenation system is not a part of<br>this Master Plan. This comment is being provided to<br>District Management. Please contact District<br>Management at 530.544.6474.        |
| 16a               | 9/2/2022 | Andy Lovell                                        | Trying to understand the irrigation. If it is used<br>in Alpine County - what is it going to be used<br>for? Flood or spray irrigation?                                                                               | Recycled water will be used for surface, aerial and<br>subsurface irrigation depending on the location of the<br>application. See as outlined Chapter 2 of the EIR for<br>project descriptions and locations.                                                                                           |

| 16b               | 9/2/2023 | Andy Lovell    | What about The Jungle? Is that all flood irrigation or spray?                | Project Component 30 - Irrigate the Jungle with<br>recycled water utilizing spray irrigation as the<br>method of water application.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |  |  |  |
|                   |          |                |                                                                              | As described in Chapter 2 of the EIR (page 2-18), the<br>jungle will be irrigated will recycled water. The<br>irrigation method will be determined as part of the<br>Nutrient Management Plan (NMP)prepared for<br>project-level analysis of Project Component 30.<br>Application methods are dependent on specific site<br>characteristics, such as topography, soils, and crop<br>management.                                                                                                                                                                                                                                                                                                                                                                                                   |  |  |  |
| 16c               | 9/2/2024 | Andy Lovell    | Is it possible to create aerosol and health hazard<br>with spray irrigation? | It is possible to create aerosol using spray irrigation.<br>The State of California Water Resources Control<br>Board permits the use of recycled water for<br>irrigation. Chapter 10 of the EIR identifies the<br>Alpine County School complex as a sensitive<br>receptor in close proximity to the District's Pasture.<br>Subsurface irrigation measures and buffer areas<br>(Project Component 16) are proposed in this area to<br>prevent exposure of sensitive receptors to recycled<br>water aerosols. The temporary containment areas<br>and application areas (Project Component 11) using<br>spray or flood irrigation methods will be fenced and<br>signed to prevent unauthorized access. These<br>standard practices are outlined in SP-33 Surface and<br>Ground water Protection Plan |  |  |  |
| 16d               | 9/2/2025 | Andy Lovell    | Where is The Jungle?                                                         | Figure 2-4 shows the location of Project Component<br>30 Irrigate the Jungle with Recycled Water.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |  |  |  |

| Table P-1         |          |                |                                                                                                                                                                                                                                                                                                                                      |                                                                                                                                                                                                                                                                                                                                                                                                         |  |

When pursue<br>permitting for more land? What does this<br>involve?                        | Nutrient Management Plans (NMPs) will be<br>generated for each Project Component that involves<br>the application of recycled waterNMPs determine the optimal application rate based<br>on site-specific characteristics.Permitting of additional land requires the approval |  |  |
|                   |           |                                                                     |                                                                                                                                                                   | from California Water Quality Control Board<br>Lahontan Region (Lahontan), California Department<br>of Fish and Game (CDFG), US Fish and Wildlife<br>Service (USFWS) and Alpine County depending on<br>the specific location.                                                |  |  |
| 19a               | 9/3/2010  | Jim Jones, District<br>Board Member                                 | Anything significant from yesterday's meeting?                                                                                                                    | Comment numbers 5 through 16 summarize the verbal public comments recorded at the Turtle Rock Park public meeting.                                                                                                                                                           |  |  |
| 20a               | 9/3/2011  | Paul Sciuto, District<br>Assistant General<br>Manager               | One question regarding safety of aerosol from spray irrigation and associated health issues.                                                                      | See response to comment 16c.                                                                                                                                                                                                                                                 |  |  |
| 21a               | 9/3/2012  | Jim Jones, District<br>Board Member                                 | When this was started there were other items<br>included that were nice to dos. How could we<br>incorporate these into Master Plan? Can they be<br>done separate? | Modification to the Recycled Water Facilities Master<br>Plan requires appropriate environmental<br>documentation with appropriate scoping and review<br>in compliance with CEQA.                                                                                             |  |  |
| 22a               | 9/4/2009  | Phillip D. Bennett,<br>Chair, Alpine County<br>Board of Supervisors | The County supports optimizing the application<br>rate for recycled water for irrigation purposes on<br>existing permitted lands in Alpine County.                | The comment will be provided to the District Board<br>for their consideration. The comment does not<br>suggest modification of the EIR. Project<br>Components 18 will optimize the application rate of<br>recycled water on existing permitted lands in Alpine<br>County.    |  |  |

| 22b               | 9/4/2010  | Phillip D. Bennett,<br>Chair, Alpine County<br>Board of Supervisors | The County has concerns with providing water to<br>irrigators in NV. The County urges the District to<br>pursue improvements to infrastructure that would<br>allow for application to existing permitted lands<br>that are not receiving recycled water. | The comment will be provided to the District Board<br>for their consideration. The comment does not<br>suggest modification of the EIR. Project components<br>4, 5 and 6 will improve conveyance systems to<br>existing permitted lands in Alpine County, which<br>will allow for additional application of recycled<br>water in the Fredricksburg System, Wade Valley and<br>the Rachettes. Project component 1 pursues<br>application of recycled water to new non-irrigated,<br>permitted land in Alpine County.                                                                                                                                                                                  |  |  |
| 22c               | 9/4/2011  | Phillip D. Bennett,<br>Chair, Alpine County<br>Board of Supervisors | Tailwater detention systems should be included in all alternatives.                                                                                                                                                                                      | The comment will be provided to the District Board<br>for their consideration. Component 21-Develop<br>Tailwater Control Systems is included in Alternative<br>2 - Master Plan Projects. The District's Board has<br>the option to include this Project Component in<br>Alternative 3 and 4. SP-33 - Surface and Ground<br>Water Protection Plan, which will be implemented as<br>part of the adopted alternative that includes Tailwater<br>Management and Containment Practices as required<br>for compliance with Lahontan's waste discharge<br>requirements and with the Nutrient Management<br>Plan (NMP) prepared for the Diamond Valley<br>portion of the project area (pages D-39 and D-40). |  |  |
| 22d               | 9/4/2012  | Phillip D. Bennett,<br>Chair, Alpine County<br>Board of Supervisors | The County supports transferring water rights to ICR to improve water quality and habitat.                                                                                                                                                               | The comment will be provided to the District Board<br>for their consideration. Alternatives 2 and 4 include<br>Project Component 14, Transfer Additional Water<br>Rights to Storage in ICR.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |  |  |
| 22e               | 9/4/2013  | Phillip D. Bennett,<br>Chair, Alpine County<br>Board of Supervisors | The County supports using piped irrigation technologies for the application of recycled water.                                                                                                                                                           | The comment will be provided to the District Board<br>for their consideration. The comment does not<br>suggest modification of the EIR. Project<br>components 3, 4, 5, 6, 11, 14 and 22 will incorporate<br>piped irrigation technologies for the application of<br>recycled water.                                                                                                                                                                                                                                                                                                                                                                                                                  |  |  |

|                   | Table P-1 |                                                                     |                                                                                                                                                                                                                   |                                                                                                                                                                                                                                                                                                                                                                                                     |  |  |

| 22f               | 9/4/2014  | Phillip D. Bennett,<br>Chair, Alpine County<br>Board of Supervisors | Pressurized water systems are highly desirable in<br>providing efficient delivery of recycled water to<br>permitted areas.                                                                                        | The comment will be provided to the District Board<br>for their consideration. The comment does not<br>suggest modification of the EIR. Project components<br>4, 5 and 6 will implement pressurized water systems<br>to provide recycled water to the Fredericksburg<br>system, Wade Valley and Ranchettes.                                                                                         |  |  |
| 22g               | 9/4/2015  | Phillip D. Bennett,<br>Chair, Alpine County<br>Board of Supervisors | The County urges the District to consider<br>expansion of the existing hydrant system to<br>provide additional access points closer to<br>residential development in the Mesa Vista and<br>River Ranch locations. | The comment will be provided to the District Board<br>for their consideration. The comment is outside the<br>scope of this EIR.                                                                                                                                                                                                                                                                     |  |  |
| 22h               | 9/4/2016  | Phillip D. Bennett,<br>Chair, Alpine County<br>Board of Supervisors | The County supports the recycled water<br>wholesale program for new permitted uses only.<br>Maintaining historical relationships with existing<br>permitted irrigators is critical.                               | The comment will be provided to the District Board<br>for their consideration. The comment does not<br>suggest modification of the EIR.                                                                                                                                                                                                                                                             |  |  |
| 22i               | 9/4/2017  | Phillip D. Bennett,<br>Chair, Alpine County<br>Board of Supervisors | The County encourages District to work with<br>NDEP regarding any diversion of recycled water<br>to NV.                                                                                                           | The comment will be provided to the District Board<br>for their consideration. The comment does not<br>suggest modification of the EIR. Diversion of<br>recycled water to irrigators in Nevada will require<br>the coordination with NDEP, which is the surface<br>and ground water regulatory agency for the State.<br>Regulations and process are disclosed in Chapters 7,<br>8 and 9 of the EIR. |  |  |
| 22j               | 9/4/2018  | Phillip D. Bennett,<br>Chair, Alpine County<br>Board of Supervisors | The County supports the transfer of water rights<br>to storage in Indian Creek. Increased flows<br>would improve water quality.                                                                                   | The comment will be provided to the District Board<br>for their consideration. The comment does not<br>suggest modification of the EIR. Project component<br>24 will pursue the transfer of additional water rights<br>to storage in ICR.                                                                                                                                                           |  |  |
| 22k               | 9/4/2019  | Phillip D. Bennett,<br>Chair, Alpine County<br>Board of Supervisors | The County supports transferring water from<br>other locations in the County including Red Lake<br>to improve water quality and habitat.                                                                          | The comment will be provided to the District Board<br>for their consideration. The comment is outside the<br>scope of this EIR.                                                                                                                                                                                                                                                                     |  |  |
| 221               | 9/4/2020  | Phillip D. Bennett,<br>Chair, Alpine County<br>Board of Supervisors | The County supports the development of biomass<br>and/or wetland sod and seed production, native<br>plant nursery and other economic development<br>opportunities.                                                | The comment will be provided to the District Board<br>for their consideration. The comment does not<br>suggest modification of the EIR. Project components<br>12 13 will pursue growing biomass crops and<br>wetland seed and sod production, respectively.                                                                                                                                         |  |  |

|                   | Table P-1 |                                                                                                                                 |                                                                                                                                                                                                                                                                                                                                                                                                                                 |                                                                                                                                                                                                                                                               |  |  |

|                   |           |               |                 | <ul> <li>irrigation regime assures the protection of<br/>groundwater resources. See the Grazing Tech Mem<br/>in Appendix F for the detailed analysis. SP-34<br/>Surface and Ground Water Protection Plan outlines<br/>the applicable monitoring actions.</li> <li>Mitigation Measure GW-1B requires that the Distriengineer the temporary containment fields (Project<br/>Component 11) in such a manner that groundwater<br/>resources are protected. The District requires a<br/>temporary containment period of no less than 24<br/>days for impoundment of approximately 95 million<br/>gallons of recycled water. The ideal containment<br/>duration is between one and 60 days to allow for<br/>management decisions. The soil hydraulic<br/>conductivity's determined for this portion of the<br/>project area may not allow for this extended period<br/>of containment without potential impact to<br/>groundwater resources. The District is required to<br/>engineer the fields in a way that assures that<br/>temporarily contained recycled water does not reac<br/>potentially high ground water levels. SP-34 Surfac<br/>and Ground Water Protection Plan outlines the<br/>applicable monitoring actions.</li> </ul> |  |  |

| 24j               | 9/8/2019  | Lisa Lee,<br>Environmental<br>Scientist, Division of<br>Financial Assistance,<br>California State<br>Resources Control<br>Board | Mitigation Measure BIO-1 includes a<br>requirement to conduct biological resource<br>assessments. This measure is being applied to<br>Components 11 and 19 that make up Master Plan<br>1 and 2. In order for Master Plan Projects 1 and 2<br>to be evaluated at project-level analyses, all<br>mitigation measures for the Master Plan Projects<br>have to include specific, feasible actions that will<br>improve adverse environmental conditions, be<br>measurable to allow monitoring, and must be<br>enforceable as stated by CEQA Section 15370.<br>Change BIO-1 to comply with CEQA. | A resource assessment was performed in April 2009<br>for the Component 11 project area. Component 11<br>has been removed from Mitigation Measure BIO-1.<br>Information has been inserted into BIO-3 Impact<br>section discussing survey results for the Component<br>11 and 19 project area. Due to the fact that surveys<br>were performed in winter/spring of 2009, additional<br>surveys shall be performed in Accordance with SP-<br>30 prior to the commencement of construction to<br>ensure no new nests/nursery sites are established and<br>impacted. |  |
| 24k               | 9/8/2020  | Lisa Lee,<br>Environmental<br>Scientist, Division of<br>Financial Assistance,<br>California State<br>Resources Control<br>Board | SP-30 is being applied to Master Plan Projects 1<br>and 2. SP-30 Is not feasible mitigation for this<br>impact. Change mitigation measure SP-30 to<br>comply with CEQA Guidelines Sections 15370.                                                                                                                                                                                                                                                                                                                                                                                           | See comment 24j                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |  |
| 241               | 9/8/2021  | Lisa Lee,<br>Environmental<br>Scientist, Division of<br>Financial Assistance,<br>California State<br>Resources Control<br>Board | Pages 13-16 states that "Sensitive receptors are<br>located over one half mile from the closest<br>sensitive receptors and odor complaints will not<br>cause odor complaints." Please clarify this<br>statement to correctly reflect the location of<br>sensitive receptors from projects sites, and the<br>potential to receive odor complaints caused by<br>the Project.                                                                                                                                                                                                                  | The statement has been revised to clarify: "Sensitive<br>receptors (located at the Alpine County School and<br>associated residential neighborhood) are located over<br>one half mile from the proposed location of the<br>containment and irrigation fields. Odor complaints<br>are not expected due to distance and the location of<br>the irrigation fields being downwind from the<br>receptors."                                                                                                                                                          |  |

|                   | Table P-1 |                                                                                                                                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |  |  |

| 25a               | 9/9/2009  | Robert Tucker, Water<br>Resource Control<br>Engineer, California<br>Regional Water<br>Quality Control<br>Board, Lahontan<br>Region | The Water Board will require a Report of Waste<br>Discharge that will describe field conditions and<br>how the pumping will be done for the<br>construction of irrigation fields with the ability to<br>pump back to HPR.<br>The Nutrient Management Plan may need to be<br>adjusted to comply with CA laws, which will be<br>reflected in the Waste Discharge Requirements.<br>Main concern is Section 4.2 the last sentence<br>states, "The drinking water standard (threshold) is<br>10 mg/l however the DISTRICT feels that it is<br>prudent to monitor for a "trigger threshold" of 7<br>mg/l allowing for alternative management<br>opportunities prior to reaching the regulatory<br>threshold." The Water Board will use the trigger<br>of a statistically significant increase in nitrate as<br>nitrogen or other constituent of concern<br>contributed from the use of recycled wastewater<br>as a trigger to consider alternative management<br>opportunities. If District wishes to maintain that<br>the 7 mg/l is prudent for the Water Board to use<br>as a trigger for response, then the CEQA<br>document should include an analysis to support<br>the use of 7 mg/l as acceptable threshold. This<br>analysis must consider other sources, alternative<br>and reasonable control measures. Otherwise we<br>encourage a NMP that reflect Water Boards may<br>impose more stringent trigger values than<br>proposed in the EIR. | Appendix F contains the NMP for Diamond Valley<br>Ranch, the portion of project area on which the<br>temporary containment fields will be constructed.<br>Existing conditions of the Diamond Valley Ranch<br>are detailed in this report. Groundwater monitoring<br>results for the Diamond Valley Ranch are referenced<br>to Appendices I and J.<br>This portion of the project area is not currently<br>permitted to receive recycled water. Lahontan will<br>issue renewed waste discharge requirements during<br>project permitting, which include the monitoring and<br>reporting requirements for the project. A Report of<br>Waste Discharge will be completed and submitted in<br>accordance with the conditions of project permitting.<br>The suggested clarifying text was inserted into the<br>Diamond Valley NMP, attached in Appendix F.<br>This text updates language in the EIR on pages 7-21,<br>D-39 and D-47. The text does not change the<br>conclusions of the analysis, but clarifies the<br>discretionary action that may be taken by Lahontan.<br>The text is:<br>"In order to determine the hydraulic loading based<br>on nitrogen, Wood Rodgers consulted "WTS-1B:<br>General Criteria for Preparing an Effluent<br>Management Plan," prepared by the Nevada<br>Department of Environmental Protection (NDEP).<br>Capacity Technical Report, Appendix 4). The<br>DISTRICT understands that State Water Boards may<br>impose a more stringent trigger value if an additional<br>factor of safety is desired." |  |  |

| 26a               | 9/9/2010 | Russ Wickwire  | The District should provide part of their West<br>fork of the Carson River allotment for the DV<br>Ranch to augment the ICR inadequate 555 AF/yr<br>water allotment because that amount is not<br>sufficient to raise the lake level above the<br>contracted minimum due to the conveyance<br>system leakage and evaporation. Each year the<br>lake level drops lower and lower below the 25%<br>level already below the legal minimum. | Comment is outside the scope of this EIR and does<br>not address specific deficiencies in the analysis nor<br>does it address Recycled Water Facilities Master<br>Plan. No response is necessary. |  |

| 27a               | 7/7/2009  | Ernie Claudio,<br>District Board<br>Member | Use of sprinkler to apply recycled water in Alpine county is potentially dangerous. | Sensitive receptors (located at the Alpine County<br>School and associated residential neighborhood) are<br>located over one half mile from the closest sensitive<br>receptors proposed location of the containment and<br>irrigation fields. Odor complaints are not expected<br>due to distance and the location of the irrigation<br>fields being downwind from the receptors. Please see<br>impact AQ-3 in EIR Chapter 13 for detailed analysis<br>(page 13-16).<br>In Alpine County, the State of California Title-22<br>regulations will apply. The recycled water produced<br>by the District conforms to the state of California's<br>recycled water regulations, which are contained in<br>Title 22 of the California Code of Regulations (Title<br>22, California Code of Regulations §60301, et seq.).<br>Untreated wastewater contains bacteria, viruses, and<br>parasites that must be removed to allow safe use of<br>recycled water. Title 22 criteria are intended to<br>prevent exposure to these organisms by any of the<br>possible mechanisms: skin contact; ingestion;<br>inhalation of infectious agents in water; or by direct<br>contact with a contaminated object. Recycled water<br>is treated to an appropriate level to protect surface<br>water and to prevent transmission of pathogens<br>through aerosols (small particles of water suspended<br>in air) from spray irrigation. Conventional and<br>widely practiced water and wastewater treatment<br>processes are capable of reducing microorganisms to<br>acceptable levels. Please see page 10-2 for a |  |  |
|                   |           |                                            |                                                                                     | discussion of the regulations as they pertain to public health and safety.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |  |  |
| 27b               | 7/7/2010  | Ernie Claudio,<br>District Board<br>Member | What irrigation method will be used for the pasture land?                           | Project Component 29, Irrigate the District Pasture<br>Land, is described on page 2-17 of the EIR. A<br>combination of aerial and surface irrigation is<br>proposed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |  |  |

## Appendix Q - CEQA-Plus Form

## INSTRUCTIONS AND GUIDANCE FOR "ENVIRONMENTAL COMPLIANCE INFORMATION"

## Introduction:

Detailed information, including statutes and guidelines on the California Environmental Quality Act (CEQA), can be obtained at <a href="http://ceres.ca.gov/ceqa">http://ceres.ca.gov/ceqa</a>. A CEQA Process Flowchart that shows interaction points between lead and responsible agencies can be found at <a href="http://ceres.ca.gov/topic/env\_law/ceqa/flowchart/index.html">http://ceres.ca.gov/ceqa</a>. A CEQA Process Flowchart that shows interaction points between lead and responsible agencies can be found at <a href="http://ceres.ca.gov/topic/env\_law/ceqa/flowchart/index.html">http://ceres.ca.gov/topic/env\_law/ceqa/flowchart/index.html</a>. In addition, State Water Board environmental staff is available to answer questions about the CEQA process. Please contact your assigned Project Manager to be directed to an appropriate environmental staff person for further clarification.

## CEQA Checklist:

All projects coming to the State Water Board for funding are considered "projects" under CEQA because the State Water Board is providing discretionary approval for that funding.

The types of CEQA documents that might apply to an applicant's project include one of the following: 1. Notice of Exemption; 2. Initial Study/Negative Declaration (or Mitigated Negative Declaration with a Mitigation Monitoring and Reporting Program [MMRP]); or 3. Environmental Impact Report (EIR) with an MMRP. The applicant must determine the appropriate document for its project and submit the additional supporting information listed under the applicable section of the <u>CEQA Checklist</u>. Please submit <u>two</u> copies of all documents. If the applicant is using a CEQA document that is older than five years, the applicant must re-evaluate environmental and project conditions, and develop and submit an updated document based on the results of that re-evaluation.

The applicant must ensure the CEQA document is specific to the project for which funding is being requested. Tier I CEQA documents, such as Program or Master Plan EIRs, may not be suitable for satisfying State Water Board requirements if these documents are not project-specific. Instead, the applicant should be submitting a Tier II CEQA document that is project-specific. If this Tier II CEQA document references pertinent environmental and mitigation information contained in the Tier I CEQA document, then the applicant must submit both documents. [NOTE: Tier I and Tier II documents refer to documents as defined under CEQA. Although the same terminology is used, these documents do not relate to the Tier I and Tier II level of reviews under the CWSRF Program.]

Each applicant, if it is a public agency, is responsible for approving the CEQA documents it uses regardless of whether or not it is a lead agency under CEQA. Non-profit organizations, however, shall only be responsible for approving the applicable project mitigation measures identified in the MMRP. For purposes of State Water Board funding, all public agencies applying for this funding shall file either a Notice of Exemption or a Notice of Determination with the Governor's Office of Planning and Research (State Clearinghouse). Stamped copies of these notices shall be submitted with the rest of the environmental documents.

If the CEQA document is linked to a National Environmental Policy Act (NEPA) document (such as an Environmental Assessment or an Environmental Impact Statement), then the applicant shall submit the additional corresponding NEPA items with either a Finding of No Significant Impact, or a Record of Decision made by the lead agency under NEPA. Note that additional information may be requested from the applicant after review of all the environmental documents to ensure the State Water Board can complete its own CEQA compliance.

## Federal Information:

CEQA requires full disclosure of all aspects of the project, including impacts and mitigation measures that are not only regulated by state agencies, but also by federal agencies. Early consultation with state and federal agencies in the CEQA process will assist in minimizing changes to the project when funding is being requested from the State Water Board. For the items that follow the <u>CEQA Checklist</u>, the applicant shall provide the information and/or reference any applicable sections from the documents being submitted to assist with environmental staff's CEQA review, as well as to provide applicant guidance on any potential concerns, and to assist with federal coordination as needed.

## 1. Federal Endangered Species Act (ESA), Section 7:

For further information on the federal ESA relating to law, regulation, policy, and notices, go to <u>http://www.fws.gov/endangered/policy/index.html</u> and <u>http://www.nmfs.noaa.gov/pr/laws/esa/</u>. Note that compliance with both state and federal ESA is required of projects having the potential to impact special status species. Although overlap exists between the federal and state ESAs, there might be additional or more restrictive state requirements. For further information on the state ESA, go to <u>http://www.dfg.ca.gov/habcon/cesa/</u>.

## 2. National Historic Preservation Act, Section 106:

The NHPA focuses on federal compliance. In addition, CEQA requires that impacts to cultural and historic resources be analyzed. The "CEQA and Archeological Resources" section from the Governor's Office of Planning and Research CEQA Technical Advice Series states that the lead agency obtains a current records search from the appropriate California Historical Resources File System Information Center. In addition, the Native American Heritage Commission (NAHC) will provide a list of Native American tribes to be contacted and that are culturally affiliated with a project area.

The NAHC can be contacted at:

915 Capitol Mall, Room 364 Sacramento, CA 95814 (916) 653-4082 3. Clean Air Act:

For CWSRF financed projects, we recommend including a general conformity section in the CEQA documents so that another public review process will not be needed, should a conformity determination be required. The applicant should check with its air quality management district and review the State Air Resources Board <u>California air emissions map</u> for information on the State Implementation Plan. For information on the analysis steps involved in evaluating conformity, please contact the environmental staff person through the assigned Project Manager.

## 4. Coastal Zone Management Act:

## For affected areas, refer to

<u>http://coastalmanagement.noaa.gov/mystate/docs/StateCZBoundaries.pdf</u>. For additional information please refer to <u>http://www.coastal.ca.gov/ccatc.html</u> and/or <u>http://www.bcdc.ca.gov/</u>.

## 5. Farmland Protection Policy Act:

The Natural Resources Conservation Service provides information on the Farmland Protection Policy Act at <u>http://www.nrcs.usda.gov/programs/fppa</u>. Please see the following website regarding the Williamson Act <u>http://www.consrv.ca.gov/dlrp/lca</u>.

## 6. Floodplain Management - Executive Order 11988:

Each agency shall provide leadership and take action to reduce the risk of flood loss, to minimize the impact of floods on human safety, health and welfare, and to restore and preserve the natural and beneficial values served by floodplains in carrying out its responsibilities. Before taking an action, each agency shall determine whether the proposed action will occur in a floodplain. The generally established standard for risk is the flooding level that is expected to occur every 100 years. If an agency has determined to, or proposes to, conduct, support, or allow an action to be located in a floodplain. The agency shall consider alternatives to avoid adverse effects and incompatible development in the floodplains. For further information, please consult the following web link: http://www.epa.gov/owow/wetlands/regs/eo11988.html.

7. Migratory Bird Treaty Act (MBTA):

The MBTA, along with subsequent amendments to this Act, provides legal protection for almost all breeding bird species occurring in the United States and must be addressed in CEQA. The MBTA restricts the killing, taking, collecting and selling or purchasing of native bird species or their parts, nests, or eggs. The treaty allows hunting of certain game bird species, for specific periods, as determined by federal and state governments. In the CEQA document, each agency must make a finding that a project will comply with the MBTA. For further information, please consult the following web link: <u>http://www.fws.gov/laws/lawsdigest/migtrea.html</u>.

8. Protection of Wetlands – Executive Order 11990:

Projects, regardless of funding, must get approval for any temporary or permanent disturbance to federal and state waters, wetlands, and vernal pools. The permitting process is usually through the

U.S. Army Corps of Engineers (USACOE), can be lengthy and may ultimately require project alterations to avoid wetlands. Applicants must consult with USACOE early in the planning process if any portion of the project site contains wetlands, or other federal waters. The USACOE Wetland Delineation Manual is available at: <u>http://www.wetlands.com/regs/tlpge02e.htm</u>. Also note that the Water Boards are involved in providing approvals through a 401 Water Quality Certification and/or Waste Discharge Requirements

(http://www.waterboards.ca.gov/water\_issues/programs/cwa401/index.shtml).

9. Wild and Scenic Rivers Act:

There are construction restrictions or prohibitions for projects near or on a "wild and scenic river." A listing of designated "wild and scenic rivers" can be obtained at <a href="http://www.rivers.gov/wildriverslist.html">http://www.rivers.gov/wildriverslist.html</a>. Watershed information can be obtained through the "Watershed Browser" at: <a href="http://cwp.resources.ca.gov/map">http://cwp.resources.ca.gov/map</a>.

10. Source Water Protection:

For more information, please visit: <u>http://epa.gov/region09/water/groundwater/ssa.html</u>.

## CALIFORNIA ENVIRONMENTAL QUALITY ACT (CEQA) CHECKLIST FOR THE APPLICANT What to Submit to your State Water Board's Project Manager

If project is covered under a CEQA Categorical or Statutory Exemption, submit a copy of the following:

- **Notice of Exemption (filed with the Governor's Office of Planning and Research)**
- List of Best Management Practices (BMPs) and their locations, if project implements BMPs
- □ Map of the project area

If project is covered under a **Negative Declaration**, submit a copy of the following:

Draft and Final Initial Study/Negative Declaration (or Mitigated Negative Declaration, if applicable)

- □ Comments and Responses to the Draft
- □ Mitigation Monitoring and Reporting Program (if using a Mitigated Negative Declaration)
- Resolution approving the CEQA documents
  - □ Adopting the Negative Declaration
  - □ Making CEQA Findings
- **Notice of Determination (filed with the Governor's Office of Planning and Research)**

If project is covered under an Environmental Impact Report (EIR), submit a copy of the following:

## Draft and Final EIR

- Comments and Responses to the Draft
- □ Mitigation Monitoring and Reporting Program (MMRP)

## Resolution approving the CEQA documents

- □ Certifying the EIR and adopting the MMRP
- Making CEQA Findings
- Adopting a Statement of Overriding Considerations for any adverse impact(s) that cannot be avoided or fully mitigated if project is implemented

**Notice of Determination (filed with the Governor's Office of Planning and Research)** 

If EIR is a joint CEQA/National Environmental Policy Act document (EIR/Environmental Impact Statement or EIR/Environmental Assessment), submit the applicable Record of Decision and/or Finding of No Significant Impact.

## State Water Resources Control Board (State Water Board) Clean Water State Revolving Fund Program

Evaluation Form for Environmental Review and Federal Coordination

## 1. Federal Endangered Species Act:

Does the project involve any direct effects from construction activities, or indirect effects such as growth inducement that may affect federally listed threatened or endangered species that are known, or have a potential, to occur on-site, in the surrounding area, or in the service area?

□ No. Discuss why the project will not impact any federally listed special status species:

Yes. Include information on federally listed species that could potentially be affected by this project and any proposed avoidance and compensation measures so that the State Water Board can initiate informal/formal consultation with the applicable federally designated agency. Document any previous ESA consultations that may have occurred with the project.

Attach project-level biological surveys, evaluations analyzing the project's direct and indirect effects on special-status species, and a current species list for the project area.

2. <u>National Historic Preservation Act:</u>

Identify the Area of Potential Effects (APE), including construction, staging areas, and depth of any excavation. (Note that the APE is three dimensional and includes all areas that may be affected by the project, including the surface area and extending below ground to the depth of any project excavations.)

Attach a current records search with maps showing all sites and surveys drawn in relation to the project area, and records of Native American consultation.

# **3.** <u>Clean Air Act:</u> Is the project subject to a State Implementation Plan (SIP) conformity determination?

□ No. The project is in an attainment or unclassified area.

Yes. The project is in a nonattainment area or attainment area subject to maintenance plans. Include information to indicate the nonattainment designation (e.g. moderate, serious or severe), if applicable. If estimated emissions (below) are above the federal de minimis levels, but the project is sized to meet only the needs of current population projections that are used in the approved SIP for air quality, then quantitatively indicate how the proposed capacity increase was calculated using population projections.

Air Basin Name:

Provide the estimated project construction and operational air emissions (in tons per year) in the chart below, and attach supporting calculations.

| Pollutant                         | Status (Attainment,<br>Nonattainment or<br>Unclassified) | Threshold of<br>Significance for the<br>Area (if applicable) | Construction<br>Emissions<br>(Tons/Year) | Operation<br>Emissions<br>(Tons/Year) |
|-----------------------------------|----------------------------------------------------------|--------------------------------------------------------------|------------------------------------------|---------------------------------------|
| Carbon Monoxide (CO)              |                                                          |                                                              |                                          |                                       |
| Ozone (O <sub>3</sub> )           |                                                          |                                                              |                                          |                                       |
| Oxides of Nitrogen                |                                                          |                                                              |                                          |                                       |
| $(NO_x)$                          |                                                          |                                                              |                                          |                                       |
| Particulate Matter                |                                                          |                                                              |                                          |                                       |
| (PM <sub>2.5</sub> )              |                                                          |                                                              |                                          |                                       |
| Particulate Matter                |                                                          |                                                              |                                          |                                       |

Attach any air quality studies that may have been done for the project.

## 4. <u>Coastal Zone Management Act:</u> Is any portion of the project site located within the coastal zone?

 $\Box$  No. The project is not within the coastal zone.

Yes. Describe the project location with respect to coastal areas, and the status of the coastal zone permit:

## 5. <u>Farmland Protection Policy Act:</u> Is any portion of the project site located on important farmland?

□ No. The project will not impact farmland.

Yes. Include information on the acreage that would be converted from important farmland to other uses. Indicate if any portion of the project site is located within Williamson Act control and the amount of affected acreage:

## 6. <u>Flood Plain Management:</u>

Is any portion of the project site located within a 100-year floodplain as depicted on a floodplain map or otherwise designated by the Federal Emergency Management Agency?

□ No. Provide a description of the project location with respect to streams and potential floodplains:

Yes. Describe the floodplain, and include a floodplain map and a floodplains/wetlands assessment. Describe any measures and/or project design modifications that would minimize or avoid flood damage by the project:

## 7. <u>Migratory Bird Treaty Act:</u>

Will the project affect protected migratory birds that are known, or have a potential, to occur on-site, in the surrounding area, or in the service area?

□No.

Yes. Discuss the impacts (such as noise and vibration impacts, modification of habitat) to migratory birds that may be directly or indirectly affected by the project and mitigation measures to reduce or eliminate these impacts. Include a list of all migratory birds that could occur where the project is located:

## 8. <u>Protection of Wetlands:</u>

# Does any portion of the project area contain areas that should be evaluated for wetland delineation or require a permit from the U.S. Army Corps of Engineers?

□ No. Provide the basis for such a determination:

Yes. Describe the impacts to wetlands, potential wetland areas, and other surface waters, and the avoidance, minimization, and mitigation measures to reduce such impacts. Provide the status of the permit and information on permit requirements:

## 9. <u>Wild and Scenic Rivers Act:</u> Is any portion of the project located within a wild and scenic river?

□ No. The project will not impact a wild and scenic river.

Yes. Identify the wild and scenic river watershed and project location relative to the affected wild and scenic river:

Identify watershed where the project is located:\_\_\_\_\_

## 10. Source Water Protection:

Is the project located in an area designated by the U.S. Environmental Protection Agency, Region 9, as a Sole Source Aquifer?

□ No. The project is not within the boundaries of a sole source aquifer.

Yes. Identify the aquifer (e.g., Santa Margarita Aquifer, Scott's Valley, the Fresno County Aquifer, the Campo/Cottonwood Creek Aquifer or the Ocotillo-Coyote Wells Aquifer):

| South Tahoe Public Utility District, Recycled Water Facilities Master Plan, EIR Meeting<br>and Field Visit Summary with California Department of Fish and Game |
|                                                                                                                                                                |

## September 21, 2009 Meeting:

HBA staff (Anders Hauge and Garth Alling) and District Staff (Hal Bird) met with California Department of Fish and Game staff at the Region 6 office in Rancho Cordova on September 21, 2009 to discuss comments on the Draft EIR prepared on the STPUD Recycled Water Facilities Master Plan.

Issues discussed were significant and unavoidable impacts identified in the EIR. The following issues were discussed:

- Deer winter range in the project area and impacts to deer movement
- Lentic and lotic enviornments as a result of groundwater quality degridation
- Clarification of the master plan and master plan projects

It was determined the CDFG would reivew the existing mitigation measures and modify accordinly. An additional site visit was set for October 1, 2009.

#### October 1, 2009 Site Visit:

A field visit was performed with staff of the District, HBA and CDGF to view the project area and to discuss project related impacts. Site specific project areas were visitied to determine the suitability of the habitat and to reivew/discuss future impacts to the enviornment from project implementation. Mitigation ratios were discussed for impacts to stream/riparian habitats and areas were reviewed for future restoration and mitigation.

Subsequent to the field meeting, DFG provided HBA with revised mitigations noting impacts would be less than significant after mitigation with the new changes.
